Editor's Preface

Ever since its publication in 1993 the *Encyclopedia of Language and Linguistics* has been an invaluable reference to my students, colleagues, and myself. The entries dealing with sociolinguistic and applied sociolinguistic topics were invariably accessible, informative, and thought provoking. If I had one reservation, it was that of having to work through ten volumes to access entries of sociolinguistic relevance, well alphabetized and indexed though the encyclopedia was. When the chance came to edit a single-volume spin-off for sociolinguistics, suitably revised, updated and extended, whilst retaining as many original articles as possible, I grabbed it with both hands. I trust the present spin-off, *Concise Encyclopedia of Sociolinguistics (CESO)* will prove as valuable a resource as the parent encyclopedia was. Debts incurred in producing *CESO* are numerous. Above all I thank the contributors, especially those who produced new articles within very tight deadlines, and those who revised earlier entries within even tighter deadlines. I am most grateful to Elsevier Science Limited for acting as host to this the first encyclopedia of sociolinguistics. In particular I thank Chris Pringle, Senior Publishing Editor, and Helen Collins, Editor, for the initiatives relating to planning of the work; Tamson Morley for her helpful and speedy support on e-mail as editorial assistant in the first part of the project; Ros Fane and the other members of the production team who turned a massive and slightly raw manuscript into a reference work. In Cape Town I incurred many debts in the process of editing: to the University of Cape Town for allowing me short periods of leave in 2001 that enabled me to work with the press at first hand at key stages; to Roger Lass who allowed me unlimited access to his office to consult or borrow his 10 volumes of the parent encyclopedia; to Sean Bowerman who assisted me in many ways to meet my teaching and administrative commitments when I was immersed in editorial duties; to Rowan Mentis, Germain Kouame, and Ginny Kerfoot who assisted with the very necessary chores of photocopying, checking of references, and the like; and most of all to my research assistant, Sarah Johnson, who instilled new admiration in me for the cheerfulness, efficiency, and computer-savvy of the young.

This volume is dedicated to the four individuals who labored over the original ten-volume encyclopedia, whom I was lucky enough to meet during a brief visit to Edinburgh a decade ago, and on whose editorial shoulders I have metaphorically stood: Ron Asher; Seamus (JMY) Simpson; Alison Bowers and Colin MacLean.

Biographical Note

Rajend Mesthrie was born in Umkomaas, a rural part of KwaZulu-Natal, and went to school there. His first university degree (in English, Mathematics, and Education) was at the University of Durban-Westville, a racially segregated university, as was customary at the time. He taught English and Mathematics at his old high school in Umkomaas, before embarking on a year of graduate education (Honors) in English Language at the University of Cape Town, where the inspirational teaching of J. M. Coetzee and others confirmed his desire for a career in Linguistics. An Anglo-American scholarship took him to the University of Texas (Austin) where he pursued his interests in General and Historical Linguistics as an MA student. The Linguistics Society of America's summer institute of 1980 at the University of New Mexico inculcated an abiding interest in Sociolinguistics in general and Variation and Contact Linguistics in particular. He has since taught English Language at the University of Durban-Westville and Linguistics at the University of Cape Town. His PhD was on the transformation of Bhojpuri in South Africa. Mesthrie has remained a 'contact sociolinguist with variationist leanings' whilst interfacing with the more 'applied' concerns of South African research. He has worked on the contact sociolinguistics of three of the major families in South Africa: the Indic (chiefly Bhojpuri); the Bantu (chiefly Fanakalo pidgin and initial Bantu-Germanic contacts); and the Germanic (chiefly English interlanguages and non-standard dialects; and early contact and code switching between Afrikaans and English). This has led to his being invited as keynote speaker at all the societies involved in southern African language studies: the Linguistics Society; Applied Linguistics Society; African Languages Association; Indological Association and the English Academy. Mesthrie has been involved in a small way in the process of political transformation in South Africa; and sees educational development as an important part of his duties. He is currently head of the Linguistics Section (of the department of Linguistics and Southern African

Languages) and deputy director of CALSSA (Centre for Applied Language Studies and Services in Africa) at the University of Cape Town; and President of the Linguistics Society of Southern Africa. He was a visiting fellow at the University of Pennsylvania on an Educational Opportunities Fellowship in 1989 and Visiting Scholar at Berkeley in 1998. He is married to Uma Mesthrie, a historian at the University of the Western Cape and is the proud father of an eight-year-old daughter, Sapna Mayuri Mesthrie.

Introduction

Sociolinguistics: History and Overview
R. Mesthrie

1. Language

The Concise Encyclopedia of Sociolinguistics (*CESO*) is intended to give a comprehensive overview of the main topics in an important branch of language study, generally known as Sociolinguistics. Linguistics may be somewhat blandly defined as the study of language. Such a characterization leaves out the all-important formulation of how such study is to be conducted, and where exactly the boundaries of the term 'language' itself lie. Broadly speaking, different branches of linguistics are concerned with language structure, acquisition, and use.

The term 'language' is generally accepted to refer to a system of arbitrary symbols used for human communication. Having 'human communication' as part of the definition of language makes it impossible to study language comprehensively without due regard to social contexts of speech. This emphasis was not always explicit in linguistics.

2. Sociolinguistics' Antecedents

While Sociolinguistics as a specially demarcated area of language study only dates to the early 1960s (see e.g., Paulston and Tucker (1997) and Shuy (1997: 23) who cite the summer of 1964 as a crucial time), attention to the social was implicit in many earlier studies. It is possible that just as most linguists accept that scholarly linguistics was first practiced in ancient India, culminating in Pāṇini's *Aṣṭādhyāyī* (ca. 500 BCE), he may prove a pioneer of sociolinguistics too. The suggestion has been made that Pāṇini's rules are, *inter alia*, 'sophisticated attempts at capturing the stylistic preferences among variants which are characteristic of any living language' (Kiparsky 1979: 1). In terms of a continuous lineage for modern sociolinguistics, however, four western traditions have been most influential: historical and comparative linguistics; anthropology; rural dialectology; and the study of mixed languages.

Historical and comparative linguists became interested in modern speech forms (or 'dialects') for the possible light they could shed on theories of language change previously based on written materials. Two branches of what is now called sociolinguistics had strong nineteenth-century antecedents: the study of rural dialects in Europe and contact between languages that resulted in new 'mixed languages.' Schuchardt and Hesseling produced their first major works on mixed languages in 1882 and 1897, respectively. But it is in the earlier, recently rediscovered work of an American librarian, Van Name (1869–70) that we find descriptions and analyses of mixed languages which reach a level of theoretical sophistication.

Even de Saussure (1857–1913), who is most frequently associated with modern structuralism, stressed in his work that language was a 'social fact,' i.e., it belonged to a realm larger than that of the individual. A society is not just the lowest common denominator of its individuals. For de Saussure, the concrete data of language (what he called *parole*) are produced by individual speakers, but 'language is not complete in any speaker; it exists perfectly only within a collectivity' (1959: 14).

In the early twentieth century, structuralists in the USA were partly motivated by the need to describe rapidly eroding American Indian languages before they became extinct. Becoming acquainted with the cultural patterns of societies that were novel to them led scholars like Franz Boas, Leonard Bloomfield and Edward Sapir to establish the foundations for studies of language, culture, and cognition. Such an anthropological perspective on language was a forerunner to some branches of sociolinguistics, especially the ethnographical approach.

The term 'sociolinguistics' appears to have been first used in 1952 by Haver Currie, a poet and philosopher who noted the general absence of any consideration of the social in the linguistic research of his day. Significant works on sociolinguistics appearing after this date include: Weinreich's influential *Languages in Contact* (a structural and social account of bilingualism) of 1953; Einar Haugen's two volume study of the social history of the Norwegian language in America (1953); and Joos (1962) on the dimensions of style.

3. Emphases in Sociolinguistics

Chomsky's insistence in the 1950s and 1960s on abstracting language away from everyday contexts

1

ironically led to the distillation of a core area of sociolinguistics, opposed to his conception of language. In a now infamous passage Chomsky (1965: 3) argued that linguistic theory should be concerned primarily with an ideal speaker-listener, in a completely homogeneous speech community, who knows its language perfectly and who is unaffected when applying his knowledge of the language in actual performance. Whilst such an approach brought significant gains to the theory of syntax and phonology, many scholars felt that abstracting away from society served limited ends which could not include an encompassing theory of human language. This period marked a break between sociolinguists with an interest in language as a communicative tool within human societies and the generativists with their interest in an idealized, non-social, psycholinguistic competence. Whereas the Chomskyan framework focused on what could be generated in language and by what means, the social approach tries to account for what can be said in a language, by whom, to whom, in whose presence, when and where, in what manner and under what social circumstances (Fishman 1971, Hymes 1971, Saville-Troike 1982). For the latter group the process of acquiring a language is not just a cognitive process involving the activation of a pre-disposition in the human brain, it is a social process as well, that only unfolds in social interaction. The child's role in acquiring its first language is not a socially passive one, but one which is sensitive to certain 'environmental' conditions, including the social identity of the different people with whom the child interacts.

Dell Hymes (1971) was the principal objector to the dominance of Chomsky's characterization of what constituted the study of linguistic competence. He suggested that a child who might produce any sentence whatever without due regard to the social and linguistic context would be 'a social monster' (1974: 75) who was 'likely to be institutionalized.' Hymes coined the term *communicative competence* to denote the human ability to use language appropriately in different settings. Hymes' interest was not just in the production of sentences but in characterizing the more social-bound aspects like the amount and volume of talk in different communities, acceptability of silence, rules for turn-taking, amount of simultaneous talk, etc. There are, in this view, rules of use without which the rules of grammar are, at best, abstractions (at worst, Hymes says, 'useless'). William Labov (1972: xiii), whose name features prominently in the discipline, expressed uneasiness about the term sociolinguistics, since in his view there can be no linguistics that is not social. Still others are slightly suspicious of the term since it privileges the linguistic over the social. One distinction that is sometimes made is that between sociolinguistics (proper) and the sociology of language. Some scholars believe that the former is part of the terrain mapped out in Linguistics, focusing on language in society for the light that social contexts throw upon language. For these scholars, the latter (Sociology of Language) is primarily a sub-part of Sociology, which examines language use for its ultimate illumination of the nature of societies. One writer (Fasold 1984, 1990) has attempted to capture this formulation by writing two scholarly books, one devoted to *The Sociolinguistics of Society* and the other to *The Sociolinguistics of Language*. Whilst there is some basis for such a partition, and something to be gained by it, in practice the boundaries between the two areas of study are so flexible as to merit one cover term. *CESO* tries to give equal coverage to both areas. Sometimes the distinction between the two orientations is expressed by the terms *macro-* and *micro-sociolinguistics*. As in other subjects, notably economics, macro-studies involve an examination of interactions at a broader level (the focus is broad, as in the study of multilingualism, or language attitudes in a community). Micro-studies examine finer patterns on a local level (e.g., conversational structure or accents in a particular community).

4. Branches of Sociolinguistics

To a large extent the sections within *CESO* cover the main concerns of the discipline: Interaction; Variation; Culture; Power and Ideology; Language Contact; Applications of Sociolinguistics. Like most editors in this series I have agonized over whether to present entries in sections or as a straight alphabetical list. It is hoped that the choice of entries within sections rather than a straight alphabetical list gives a better sense of the subject, without getting in the way of looking up specific entries.

The first section *Foundations of Society and Language* is concerned with defining and approaching the key concepts language and society, from the vantage points of the parent disciplines of Linguistics, Sociology, Anthropology, and Social Psychology. Sociolinguists have learned to live with the situation that, after extensive research and debate, key terms like 'language,' 'native speaker,' and 'society' are still fuzzy concepts. The next section covers the subfield that I believe has gained the most ground in the last 20 years, viz. the study of *Language and Interaction*. Here the emphasis lies on the principles of conversation, the ways in which people make adjustments in speech when interacting with others and the ways in which societies differ in their assumptions about, expectations for, and use of language. The next two sections of the encyclopedia cover what is for many the heartland of the discipline: a close attention to the ways in which a language may vary. The first of these, *Language Variation: Style, Situation, Function* deals with the

importance of contextual factors in determining different registers, styles, and genres. It also deals more specifically with the use of language for specific domains and functions as in advertising, religion, business, and e-mailing. The second section on the theme of variation, *Language Variation and Change: Dialects and Social Groups* deals with the finely-nuanced differences within a language according to social groupings, especially class, gender, ethnicity, and region. The variationist interest in language change is also represented in this section. The section *Language Contact* stresses the reality that societies are rarely monolingual; languages exist amidst other languages. The idea of a pure and self-contained language is a poor simplifying assumption, compared with the challenges of studying the ways in which speakers of different languages influence each other, and how multilingualism is 'managed' by speakers at a microlevel and by societies at a macrolevel. The next three sections are more obviously cross-disciplinary, rooted in Sociolinguistics as well as Sociology, Politics, and Education. *Language, Power, and Inequality* deals with the ways in which language is entrenched in, and entrenches, relations of dominance in societies. For critical sociolinguists of this school, language does not simply reflect reality; society is not always 'out there' independent of a language; certain contexts are created by language. Moreover, there is a sense in which language *mis*represents society, concealing the nature of certain relations of dominance. *Language Planning, Policy, Practice* deals with the macrosociolinguistic issues of the choice of a national language or languages, and the ways in which languages can be developed to face the challenges of communication in an era spanning political independence, nation-building, and globalization. *Language and Education* stresses the close relation between sociolinguistics and education, especially in relation to validating the languages and dialects that children bring to the school. Ideas from interactionists, variationists, contact linguists, and critical sociolinguists are of some import to the well-trained language teacher. The remaining parts of the encyclopedia are meta-theoretical. *Methods in Sociolinguistics* gives an account of (a) statistical approaches that are vital to a discipline that is largely (but by no means exclusively) steeped in empirical tradition, and (b) the methods of data gathering and traditions of analysis underpinning the various sections cited above. *The Profession* gives a sense of sociolinguistics as a profession, by reference to its key journals, societies, conferences, and centers. It also provides profiles of leading sociolinguists past and present. As this is a young discipline, it is a pleasure to be able to honor many living sociolinguists. However, there is an accompanying pitfall that some deserving scholars have not been included for one reason or another.

The scholars chosen are those whose work has come to international recognition via writing in, or being translated into, English. This might be unfair to sociolinguists that have resisted such linguistic hegemony. On the whole the list must be seen as representative rather than definitive.

5. Applications of Sociolinguistics

There are many practical outcomes of sociolinguistic research, which are described in entries spread throughout *CESO*. One section is specifically 'applied' in focus (*Language and Education*), since contributions of sociolinguists in this arena are numerous, covering the home language–school language interface, the public debates about Standard English and less feted varieties like Ebonics, an understanding of educational failure, enhancing gender sensitivity in male dominated classrooms, and so forth. Entries within *CESO* detail other ways in which sociolinguists have given publicly of their expertise. Sociolinguists provide expert testimony in courtrooms based on their studies of discourse and accent patterns (see *Forensic Phonetics and Sociolinguistics*; *Discourse Analysis and the Law*); contribute to the growing attempts to save endangered languages (see *Reversing Language Shift*; *Salvage Work (Endangered Languages)*); cooperate with other educationists in government and non-government committees on language (see *Language Development*; *Language Adaptation and Modernization*; *Language Planning: Models*); and contribute to cultural vitality by recording, describing and popularizing rural speech and varieties that are either denigrated or not recognized in the popular mind as 'legitimate' language (see *Dialect and Dialectology*; *Pidgins and Creoles: An Overview*). This smooth and holistic interface between theory and application promises health and longevity to a young discipline.

Foundations of Society and Language

Anthropological Linguistics
E. Keating

Anthropological linguistics, or as it is sometimes called, linguistic anthropology, is a cross-disciplinary and cross-cultural approach to the study of language. The goals are understanding and describing the important ways that language organizes social life and cultural ways of thinking, including the interpretation of others' utterances and behavior. Anthropological linguistics is an area of research concerned particularly with the social production and negotiation of meaning, including both an exploration into relationships between linguistic structures and an exploration into the role of context in communicating and understanding them. Linguistic anthropologists study a wide range of phenomena, including relationships between language and status, who can say what to whom and in what context, language genres, language and gender, language and institutions, language and the transmission of knowledge, the acquisition of language, multilingualism, identity, creolization, linguistic ideologies, literacy, linguistic borrowing, language change, the social valuing of particular language practices, the esthetics of language production, notions of the self as produced through language, cognition, gesture, the role of space in communication, as well as what constitutes competence, performance, participation, and even language itself. There is thus a considerable overlap with the field of sociolinguistics.

The study of language within particular contexts has always been recognized as a crucial means to understand linguistic structures. However, for those linguists working within the Chomskyan perspective, the social parameters of language use have not been considered important to theorizing meaning production. This situation has resulted in the further development of the field of Anthropological Linguistics as a center for research into theories of meaning production that include social context. The study of language has always been important to anthropologists, particularly those anthropologists whose tradition follows from the work of the German-born Franz Boas on Native American languages (see *Boas, Franz*).

Anthropological Linguistics is an approach that recognizes meaning as a process negotiated between interactants rather than as something that exists within the individual or language structures. As argued by Wittgenstein, 'meaning is use' (1958: paragraph 43), and utterances are only understandable in relation to activities. To anthropological linguists, language is assumed to be not only a rule-governed system with its own internal logic (learned by every child in the community), but also a system of tools for the constitution of social life. This includes language structure, language practice, visual codes, the interface between verbal and visual codes, and relationships to habitual modes of thought. In all societies children develop concepts of a 'socioculturally structured universe' through their participation in language activities and acquisition of language (Ochs 1988: 14). To engage in an act of communicating is 'to take up a position in a social field in which all positions are moving and defined relative to one another' (Hanks 1996: 201). Talk is designed and interpreted as meaningful in relation to particular sequences and contexts. For example, in a courtroom in the US the meaning of a particular utterance is dependent on its sequential placement in ongoing discourse, on the participants, and on how conventional interpretations of meaning are manipulated, confirmed, or resisted by those authorized to speak in order to shape meanings. In Samoan political meetings participants similarly negotiate how to define and assign responsibility for socially disruptive acts, a process that involves linguistic strategies. Ways in which agency is grammatically expressed in such contexts are connected not only to different points of view, but to local political practices (Duranti 1994). Ethnographic accounts of communicative events cross culturally have repeatedly shown the importance of context in understanding language practices. Utterances and actions are context-shaped and certain features of language invoke contextual assumptions. Indexical relations are an important area of research, since interpretation of deictics is impossible outside of a particular context (see *Context*).

There are several important methodological and theoretical paradigms that influence work in

5

Anthropological Linguistics. These include the view of language as social action developed by John Austin, where language is a 'force' and in the production of an utterance a speaker performs an action (e.g., reminding, denying, criticizing, pledging, swearing, urging, demanding, apologizing, greeting, and so on), a view now expanded beyond the individual's single utterance to include how each turn at talk makes relevant some next action by another. Anthropological linguists have been influenced by Wittgenstein's notion of language as a game with numerous strategies available to participants, Goffman's work on social situations and the production and maintenance of understanding, and Garfinkel's studies of the tacit procedures members of a society use to make sense of everyday actions. The work of Bakhtin (see *Bakhtin, Mikhail M.*) investigating relationships between past and present utterances and the facility of language for presenting multiple perspectives has been important to many linguistic anthropologists, as well as the work of Bourdieu (see *Bourdieu, Pierre*) on the importance of habitual, embodied, everyday practices, Foucault's (see *Foucault, Michel*) ideas on the evolution of relationships between individuals and institutions, and the work of Vygotsky on the development of human cognition from interactions with others and with tools. Anthropological linguistics draws on ideas developed by the Prague school of linguistics, particularly Jakobson's formalizations of inquiry into relationships between form and content as consequential to meaning, for example, how poetic patterns can create semantic relations. The work of discourse analysts on texts and the work of conversation analysts on talk-in-interaction have been influential, in order to understand how language is manipulated and how language activities are locally managed moment-by-moment, including recipient design of utterances, code-switching, and the role of participation frameworks. Work in the paradigm known as the ethnography of speaking (Gumperz and Hymes 1972) has also been influential in studying communication as a cultural practice (see *Ethnography of Speaking*). Anthropological linguists typically combine ethnography with a number of other methods described above, including linguistic analysis at the phrase and morpheme level.

Anthropological linguistics has a close affinity to sociolinguistics, a field also concerned with the social uses of language. It is also related to studies being conducted in communication, ethnomusicology, sociology, applied linguistics, linguistics, sociology, psychology, education, cognitive science, and performance studies. Language is a pervasive aspect of daily life. Scarcely any society has not felt the effects of new communicative technologies. These new tools have been extremely important in the practice of Linguistic Anthropology, in terms of providing rich new opportunities for data collection and analysis, and enhancing our understanding of language.

Attitudes and Behavior

W. S. Bainbridge

Between words and deeds there is a gap; the attitudes people express often seem contradicted by the behavior in which they engage. The problem has been examined intensively within sociology and

social psychology, yet it is of great importance for linguistics. If what people say is very different from what they do, how can we know what they really mean?

1. The Problem

In the early 1930s, Richard La Piere conducted an influential study that cast serious doubt on the trustworthiness of verbal responses to questionnaires. In the company of an English-speaking Chinese couple, he sought service at 251 American hotels and restaurants, and on only one occasion was it refused. Later, he sent a brief survey to the places they had visited, asking, 'Will you accept members of the Chinese race as guests in your establishment?' Of the 128 that replied fully, 118 said no. As measured by a questionnaire item, the respondents appeared to have strong antipathy to the Chinese, but as measured by actual behavior, they did not. La Piere argued that 'social attitudes are seldom more than a verbal response to a symbolic situation. For the conventional method of measuring social attitudes is to ask questions (usually in writing) which demand a verbal adjustment to an entirely symbolic situation.'

DeFleur and Westie (1963) note that social scientists have never agreed what the word 'attitude' means and, while widely used, it is a highly unsatisfactory scientific concept. In the seventeenth century, they say, 'attitude' was the physical positioning of an artist's subject with respect to the background, but the meaning was gradually extended to include the mental positioning of a person toward any issue. It is a fact of language that terms originally with physical meaning often come to refer to emotional and mental situations. For example, someone who has a positive attitude toward political party X is positively inclined toward it, wants to go in the same political direction, and is very far from the position taken by party Y. Social philosophers adopted 'attitude' in the nineteenth century, and by the 1930s batteries of questionnaire items had been developed that supposedly measured various attitudes. Shunning more subtle definitions, some operationalists decided that attitudes were simply whatever these scales measured.

DeFleur and Westie distinguish two more refined approaches: probability conceptions and latent process conceptions. The probability conception avoids any discussion of what might be going on inside the mind of a respondent, but focuses instead on the consistency of his or her behavior, including verbal utterances. To say that a person has an attitude is merely to note a measure of consistency in some particular sphere of behavior. For example, anti-Mexican prejudice would be revealed in consistent rejection of Mexicans, consistently expressing discomfort in the presence of Mexicans, and utterance of anti-Mexican epithets.

The more ambitious latent process conception says an attitude is a somewhat coherent constellation of cognitive events and structures, within the mind of the respondent, that shape behavior of all relevant kinds. Thus, an attitude cannot be directly observed but must be inferred. An attitude concerning a class of objects is the meaning that class has for the person, with a stress on how the individual evaluates the class, whether positively or negatively. Some versions of this conception hold that attitudes are encoded verbally in the brain, and that when people say how they feel about something they are merely giving voice to words already held within their minds. Clearly, the concept of attitude is deeply implicated in debates over the importance of language in shaping human behavior.

Despite the definitional problems, attempts have been made to summarize the conclusions of many research studies to see how often behavior is congruent with attitudes. Richard Hill (1981) examined several of these summaries and concluded that many research studies that were careful in conceptualization and research methodology showed a substantial positive correlation between attitudes and behavior. While we cannot assume that any particular attitude will strongly predict the logically related behavior, in general the connection is far from insignificant. The question then becomes: What factors give strength to the relationship between attitudes and behavior, and what factors weaken it?

2. Sources of Congruence and Incongruence

Several things can intervene between verbal attitudes and overt acts, thus reducing the congruence between them. One is time; a person can favor one candidate when the pollster knocks at the door, but another candidate several days later when the election is held. The congruence may be greatest if the verbally expressed attitude and overt behavior are at the same level of generality; a person may usually favor one political party, but may occasionally vote for a particular attractive candidate from another party. Behavior may be influenced by multiple attitudes about different aspects of it; a voter may oppose some policies of a candidate and favor others, so the pollster will have to ask about several different attitudes, and find some method of weighting them in the proper combination before a perfect prediction of voting behavior can be expected.

Speech itself is a kind of behavior, and people often use words to achieve something with their listeners, rather than to express inner thoughts and feelings directly. Put baldly, people may lie. Christie and Geis (1970) have given deceitful interaction strategies a more elegant and scientific cloak by calling them *Machiavellianism*, after the Italian social philosopher who advocated that rulers follow such policies, Niccolò Machiavelli. Less blatantly, people

may possess *response sets,* habitual ways of interacting that have the effect of distorting expression. For example, *acquiescence* is the tendency to agree with what another person says, and *social desirability bias* is the tendency to limit one's utterances to those that are socially accepted. When verbally expressed attitudes concern topics about which the community and the listener have strong feelings, they are unreliable gauges of behavior.

Apparent discrepancies between attitudes and behavior may also arise when researchers force people to express attitudes on matters about which they know and care nothing. Howard Schuman and Stanley Presser (1980) showed that this problem can be explored by experimenting with 'don't know' responses in telephone interviews. In one survey, they presented a forced-choice question about the obscure Agricultural Trade Act of 1978 in two forms. When asked merely if they favored or opposed the act, 69 percent of respondents volunteered that they did not know, but when explicitly offered a 'don't know' response, fully 90 percent of them took it, a difference of 21 percentage points. In a replication study, similar results were obtained about the little-known Monetary Control Bill of 1979. Both studies revealed that respondents' level of education shaped reported attitudes when the 'don't know' response was not offered, educated people being significantly more likely to volunteer that they did not have an attitude. Thus, spurious attitudes elicited by poorly designed questions may introduce serious biases into research. (See *Attitude Surveys: Question–Answer Process*).

Problems are not limited to the validity of verbal attitude measures, and, as Allen Liska (1974) notes, equal problems plague measures of behavior. Many research studies ask respondents for verbal reports about their own behavior. But, just as respondents may misrepresent or be confused about their feelings, they may distort their behavior, often in unpredictable ways. Teenagers responding to questions about delinquent behavior may conceal their illegal deeds from an adult interviewer, but within a peer group that confers status for bravery, they may magnify them. Respondents may not use the same definitions of behavior as did the authors of a questionnaire. For example, children often engage in trivial fights with each other, and the maturing teenager may be quite uncertain whether he or she has been guilty of 'assault.' A famous questionnaire written by criminologist Travis Hirschi told the teenage respondents not to count fights with a sister or brother, but let them include fisticuffs with a first cousin or close friend.

Among the most hotly debated discrepancies between self-reported and externally observed behavior concerned the correlation several social variables have with rates of crime. For example, members of lower social classes are disproportionately repre-

sented among inmates of prisons, while several self-report studies of juvenile delinquency in the general population show no social class differences. Hindelang et al. (1979) argue that the offenses of the two groups are simply not comparable, the prisoners being incarcerated for very serious crimes, while the delinquency questionnaires concern trivial violations likely to have been committed by substantial fractions of the population.

One factor that can increase the correspondence between attitudes and behavior is social support, as research on alcohol drinking by Rabow et al. (1987) demonstrated. Research subjects' attitudes were evaluated by agree–disagree survey items like, 'Social occasions seem more pleasant when people are drinking,' and behavior was measured by self-reports of how many drinks had been imbibed in the previous month. Social support for drinking was measured by items like, 'Nearly everybody I know expects me to offer alcoholic beverages when they are guests in my home.' Pro-alcohol attitudes were associated with actual drinking, as was social support for drinking, and there seemed to be a complex interaction between attitudes and social support, with social support perhaps strengthening the connection between attitudes and behavior.

To bridge the gap between words and deeds, a number of investigators have postulated an intervening variable, *behavior intention.* A person may possess a variety of attitudes relevant to a particular behavior; for example, voting in an election will be shaped by attitudes toward the candidates, the parties, the particular issues emphasized in the campaign, and the political orientations of the voter's friends and family. All these combine in a complex way to determine how the person intends to vote. Barring some mistake in the voting booth, this is how the person will vote. But many kinds of behavior not only depend on intentions; resources and opportunities may also be important. A good example, studied by Christian Ritter (1998) is illegal drug use. Obviously, a person cannot make good on an intention to use a particular drug if the drug is not available, and Ritter's research indicates that availability interacts in a complex way with other factors in determining the connection between attitudes and behavior.

3. The Rhetoric of Attitude–Behavior Congruence

Several writers have pointed out that people may engage in various mental gymnastics to justify the inconsistencies between their verbal attitudes and their overt behavior. In a highly influential essay, Gresham Sykes and David Matza (1957) explored five techniques of neutralization which youth may employ to justify commission of delinquent acts while professing adherence to conventional morality. Indeed, several studies had indicated that juvenile

delinquents frequently express verbal support for the very norms they violate. Sykes and Matza note that norms generally are not categorical imperatives, but highly conditional upon social circumstances. Thus, there is room for rhetoric to separate the word from the deed.

First, the delinquent can 'define himself as lacking responsibility for his deviant actions,' perhaps by invoking 'accident,' the actions of others, or unavoidable conditions, saying, in effect, 'I didn't mean it.' Second, the delinquent can deny that real injury took place, for example, by redefining auto theft as 'borrowing.' Third is denial of the victim, often through claims that the deed was a form of rightful retaliation or punishment of someone who 'asked for it.' Fourth, the delinquent may condemn his condemners, asserting that courts and police are corrupt, thus changing 'the subject of conversation in the dialogue.' And fifth, the delinquent can appeal to higher loyalties, invoking, for example, the claims of friendship over those of law to 'never squeal on a friend.' Sykes and Matza assert that these five techniques of norm neutralization substantially lessen the effectiveness of social controls and produce delinquent behavior.

A very different rhetorical problem that has fascinated researchers is the difficulty of understanding a person's true attitudes when the norms concerning expression of feelings change. For example, modern societies have recently and quickly decided to prohibit not only racial slurs, but also sober public statement of views that races differ in qualities like intelligence. Polite public discourse, therefore, has no room for overt racism. However, a few public issues concerning race have remained discussable, and some social scientists argue they have become vehicles for *symbolic racism*. For example, a public issue for several years in the USA was the busing of pupils across cities for purposes of achieving racial balance in the schools. A racist could no longer directly disparage members of another group, but socially acceptable attitudes against the policy of busing could give voice to the suppressed bigotry.

As Lawrence Bobo (1983) has argued, however, racial attitudes are not mere prejudice, but may reflect very real economic, social, and political conflict. Many social scientists used to believe, perhaps out of a naive sense of optimism, that racial and ethnic antagonism reflected little more than ingrained prejudice, unreasonable ideas, and feelings transmitted from one generation to the next. Supposedly, once members of different groups have been taught to be tolerant of each other, the prejudice would melt away. Public campaigns promoting liberal ideologies were supposed to help achieve this attitudinal change, but this strategy ignored the possibility that the groups were locked in inescapable competition for scarce resources. Thus, an important but scientifically questionable part of the concept of attitudes was that purely symbolic appeals could transform human behavior because the attitudes that were believed to shape behavior were mere symbols in the minds of the populace.

4. The Case of Religion

Perhaps the classic example of a system of symbols that is supposed to shape behavior powerfully is religion. In church sermons, we are told to love our neighbor and to obey the ten commandments. Anti-crime attitudes are presumably supported by the belief in the Devil and the fires of Hell, taught by many churches. Travis Hirschi and Rodney Stark (1969), authors of the most famous study on the topic, noted that religion might strengthen moral values, instill the belief that one's fellows deserve fair and just treatment, and promote acceptance of legal authority. But when Hirschi and Stark examined the questionnaire responses of thousands of California high school students, they found no evidence for these propositions. Students who believed in the existence of the Devil and the afterlife, and students who attended church frequently, were no less likely than their irreligious peers to have committed acts of juvenile delinquency. Thus, the societal institution reputed to be most directly responsible for instilling good attitudes, the church, had apparently failed in its task. Or, possibly even more shocking, verbally transmitted attitudes just do not matter in determining behavior.

Many sociologists quickly accepted the findings of this study, perhaps because they themselves are irreligious, and textbooks on criminology and juvenile delinquency seldom mention religion at all. But in the 1970s, a series of research findings and theoretical arguments began to add significant complexity to the picture. Replications of the Hirschi and Stark research gave different results depending upon where they were done: studies performed in the Pacific region of the USA showed no capacity of religion to deter delinquency, while studies done elsewhere revealed a significant religion effect. The key study was done by Stark and two of his graduate students, who were able to examine a massive survey dataset that came from questionnaires administrated to clusters of high school students across the USA. It not only verified the geographic differences, but connected them to the general level of religiousness in the community. Where most young people attend church and possess religious faith, religiousness correlates negatively with delinquency. But in highly secular communities where only a minority are religious, religion does not deter delinquency. Thus, the importance of social support as a variable intervening between attitudes and behavior was confirmed.

9

Other factors turn out to be important as well. Burkett and White discovered that religion continues to affect behavior, even in irreligious communities, if the behavior involves 'victimless crimes,' which may be better defined as hedonistic acts that are dangerous primarily to oneself: illegal drug use and heavy alcohol drinking. Hoge and De Zulueta (1985) suggest that the salience of the particular kind of behavior for religion is also important, religion having its most robust effects on attitudes about family life, sexuality, and personal honesty. However, the reader should not assume that research has cleared up all the mysteries, and sociologists are very far from a full understanding of how religiously transmitted attitudes affect behavior. One thing is quite clear, however. Without support from other social and psychological factors, religiously-instilled attitudes lack power to prevent people from taking actions they think may benefit them, even in defiance of societal norms. Thus, words alone cannot control deeds.

Bilingualism, Individual

F. Grosjean

Few areas of linguistics are surrounded by as many misconceptions as is bilingualism. Most people think that bilingualism is a rare phenomenon found only in such countries as Canada, Switzerland, and Belgium and that bilinguals have equal speaking and writing fluency in their languages, have accentless speech, and can interpret and translate without any prior training. The reality is in fact quite different: bilingualism is present in practically every country of the world, in all classes of society and in all age groups; in fact, it has been estimated that half the world's population is bilingual. As for bilinguals themselves, the majority acquired their languages at various times during their lives and are rarely equally fluent in them; many speak one of their languages less well than the other (and often with an accent) and many can only read or write one of the languages they speak. Furthermore, few bilinguals are proficient interpreters and translators.

In this article many facets of the bilingual individual will be discussed; the focus will be on the stable bilingual adult, that is the person who is no longer in the process of acquiring a second or third language. First the bilingual person in terms of

language knowledge and use will be described. Then, the bilingual's linguistic behavior when communicating with monolinguals and with other bilinguals will be examined. A certain number of issues in the psycholinguistics and neurolinguistics of bilingualism will be discussed, and the article will end with a brief overview of the attitudes, behaviors, and personality of the bilingual individual.

1. Describing the Bilingual

Although a few researchers have defined bilinguals as those who have native-like control of two or more languages, most others agree that this position is not realistic. If one were to count as bilingual only those people who pass as monolinguals in each of their languages, one would be left with no label for the vast majority of people who use two or more languages regularly, but who do not have native-like fluency in each. This has led researchers to propose other definitions of bilingualism, such as: the ability to produce meaningful utterances in two (or more) languages, the command of at least one language skill (reading, writing, speaking, listening) in another language, the alternate use of several languages, etc. This article will define as bilingual those people who use two (or more) languages (or dialects) in their everyday lives. (Throughout this entry, dialects are subsumed under the term 'language.') Thus, this definition includes people ranging from the migrant worker who speaks with some difficulty the host country's language (and who cannot read and write it) all the way to the professional interpreter who is totally fluent in two languages. In between is found the foreign spouse who interacts with friends in his or her first language, the scientist who reads and writes articles in a second language (but who rarely speaks it), the member of a linguistic minority who uses the minority language only at home and the majority language in all other domains of life, the deaf person who uses sign language with her friends but a signed form of the spoken language with a hearing person, etc. Despite the great diversity that exists between these people, all share a common feature: they lead their lives with two (or more) languages. (Bilinguals who are no longer using their different languages but who have retained knowledge of them will be termed 'dormant bilinguals.')

The reasons that bring languages into contact and hence foster bilingualism are many: migrations of various kinds (economic, educational, political, religious), nationalism and federalism, education and culture, trade and commerce, intermarriage, etc. These factors create various linguistic needs in people who are in contact with two or more languages and who develop competencies in their languages to the extent required by these needs. In contact situations it is rare that all facets of life require the same language (people would not be

bilingual if that were so) or that they always demand two languages (language A *and* B at work, at home, with friends, etc.). In fact, bilinguals acquire and use their languages for different purposes, in different domains of life, with different people. It is precisely because the needs and uses of the languages are usually quite different that bilinguals rarely develop equal fluency in their languages. The level of fluency attained in a language (more precisely, in a language skill) will depend on the need for that language and will be domain specific. It is thus perfectly normal to find bilinguals who can only read and write one of their languages, who have reduced speaking fluency in a language they only use with a limited number of people, or who can only speak about a particular subject in one of their languages. This explains in part why bilinguals are usually poor interpreters and translators. Not only are specific skills required, but interpretation and translation entail that one has identical lexical knowledge in the two languages, something that most bilinguals do not have. Certain domains and topics are covered by the lexicon of one language, others by the lexicon of the other language, and some few by the two. Interpreting and translating when one lacks the appropriate vocabulary and the necessary skills is thus something that bilinguals find difficult.

The failure to understand that bilinguals normally use their languages for different purposes, with different people, and in different domains of life has been a major obstacle to obtaining a clear picture of bilinguals and has had many negative consequences: bilinguals have been described and evaluated in terms of the fluency and balance they have in their two languages; language skills in bilinguals have almost always been appraised in terms of monolingual standards; research on bilingualism has in large part been conducted in terms of the bilingual's individual and separate languages; and, finally, many bilinguals evaluate their language competencies as inadequate. Some criticize their mastery of language skills, others strive their hardest to reach monolingual norms, others hide their knowledge of their 'weaker' language, and most simply do not perceive themselves as being bilingual even though they use two (or more) languages in their everyday lives.

Researchers are now starting to view the bilingual not so much as the sum of two (or more) complete or incomplete monolinguals but rather as a specific and fully competent speaker–hearer who has developed a communicative competence that is equal, but different in nature, to that of the monolingual. This competence makes use of one language, of the other, or of the two together (in the form of mixed speech; see below) depending on the situation, the topic, the interlocutor, etc. This in turn has led to a redefinition of the procedure used to evaluate the bilingual's competencies. Bilinguals are now being studied in

terms of their total language repertoire, and the domains of use and the functions of the bilingual's various languages are being taken into account.

It should be noted finally that as the environment changes and the needs for particular language skills also change, so will the bilingual's competence in his or her various language skills. New situations, new interlocutors, and new language functions will involve new linguistic needs and will therefore change the language configuration of the person involved. Extreme cases of restructuring are language forgetting and a return to functional monolingualism, be it in the person's first, second, or third language.

2. The Bilingual's Linguistic Behavior

One of the most interesting aspects of bilingualism is the fact that two (or more) languages are in contact within the same person. This phenomenon, which has led to a vast body of research, can best be understood if one examines the bilingual's various language modes. In their everyday lives, bilinguals find themselves at various points along a situational continuum which induce different language modes. At one end of the continuum, bilinguals are in a totally monolingual mode in that they are communicating with monolinguals of one—or the other—of the languages that they know. At the other end of the continuum, bilinguals find themselves in a bilingual language mode in that they are communicating with bilinguals who share their two languages and with whom they normally mix languages (i.e., code-switch and borrow; see below). For convenience, this article refers to the two end points of the continuum when speaking of the monolingual or bilingual language modes, but it should be kept in mind that these are end points and that intermediary modes do exist. This is the case, for example, when a bilingual is speaking to another bilingual who never mixes languages, or when a bilingual is interacting with a person who has limited knowledge of the other language. It should also be noted that bilinguals differ among themselves as to the extent they travel along the continuum; some rarely find themselves at the bilingual end whereas others rarely leave this end (for example, bilinguals who live in tight-knit bilingual communities where the language norm is mixed language).

2.1 The Monolingual Language Mode

In this mode, bilinguals adopt the language of the monolingual interlocutor(s) and deactivate their other language(s) as completely as possible. Bilinguals who manage to do this totally and, in addition, who speak the other language fluently and have no foreign accent in it, will often 'pass' as monolinguals. Although such cases are relatively rare, it is precisely these that have led people to think that bilinguals are (or should be) two monolinguals in one person. In fact, deactivation of the other language is rarely total as is clearly seen in the interferences bilinguals produce (these are also known as between-language deviations). An interference is a speaker-specific deviation from the language being spoken due to the influence of the other 'deactivated' language. Interferences can occur at all levels of language (phonological, lexical, syntactic, semantic, pragmatic) and in all modalities (spoken, written, or sign) (see *Language Transfer and Substrates*). They are of two kinds: static interferences which reflect permanent traces of one language on the other (such as a permanent accent, the meaning extensions of particular words, specific syntactic structures, etc.) and dynamic interferences which are the ephemeral instrusions of the other language (as in the case of the accidental slip on the stress pattern of a word due to the stress rules of the other language, the momentary use of a syntactic structure taken from the language not being spoken, etc.) Examples of interferences produced by a French person speaking English are as follows. At the phonetic level, pronouncing *Sank evven for dees* instead of *Thank heaven for this*; at the lexical level, using *corns* (from French *cornes*) instead of *horns* in *Look at the corns on that animal!*; at the syntactic level, saying *I saw this on the page five* (instead of *on page five*), and in writing, misspelling *adress* or *appartment* (based on the French *adresse* and *appartement*).

In addition, if one of the bilingual's languages is mastered only to a certain level of proficiency, deviations due to the person's interlanguage (also known as within-language deviations) will also occur. These include overgeneralizations (for example, taking irregular verbs and treating them as if they were regular), simplifications (dropping pluralization and tense markers, omitting functions words, simplifying the syntax, etc.) as well as hypercorrections and the avoidance of certain words and expressions. Between- and within-language deviations are clearly observable when bilinguals are in a monolingual language mode but they also occur in the bilingual language mode (see below). It should be noted finally that both types of deviations, although sometimes quite apparent (such as a foreign accent), usually do not interfere with communication. This is because bilinguals develop their languages to the level of fluency required by the environment. Deviations in bilingual speech are thus of the same nature as slips of the tongue and hesitation phenomena. They are present but do not usually affect communication.

2.2 The Bilingual Language Mode

In this mode, bilinguals interact with one another. First they adopt a language to use together, what is known as the 'base language' (also the 'host' or 'matrix' language). This process is called 'language choice' and is governed by a number of factors: the

interlocutors involved (i.e., their usual language of interaction, their language proficiency, language preference, socioeconomic status, age, sex, occupation, education, kinship relation, attitude toward the languages, etc.); the situation of the interaction (location, presence of monolinguals, degree of formality and of intimacy), the content of the discourse (topic, type of vocabulary needed), and the function of the interaction (to communicate information, to create a social distance between the speakers, to raise the status of one of the interlocutors, to exclude someone, to request something, etc.). Language choice is a well-learned behavior (a bilingual rarely asks the conscious question, 'Which language should I be using with this person?') but it is also a very complex phenomenon, which only becomes apparent when it breaks down. Usually, bilinguals go through their daily interactions with other bilinguals quite unaware of the many psychological and sociolinguistic factors that interact to help choose one language over another. The base language can change several times during a single conversation if the situation, topic, interlocutor, etc., require it.

Once a base language has been chosen, bilinguals can bring in the other language (the 'guest' or 'embedded' language) in various ways. One of these ways is to code-switch, that is to shift completely to the other language for a word, a phrase, a sentence. (For example, *Va chercher Marc and bribe him avec un chocolat chaud with cream on top* (Go get Marc and bribe him with a hot chocolate with cream on top).) Code-switching has long been stigmatized, and has been given a number of pejorative names such as Franglais (the switching between French and English) or Tex–Mex (the switching between English and Spanish in the southwestern part of the USA). The consequence of this has been that some bilinguals never switch while others restrict it to situations in which they will not be stigmatized for doing so. During the late 1980s and early 1990s code-switching has received considerable attention from researchers (see *Code-switching: Overview*). For example, sociolinguists have concentrated on when and why switching takes place in the social context. Reasons that have been put forward are: to fill a linguistic need, to continue the last language used, to quote someone, to specify the addressee, to exclude someone from the conversation, to qualify a message, to specify speaker involvement, to mark group identity, to convey emotion, to change the role of the speaker, etc. Linguists, on the other hand, have sought to study the types of code-switches that occur (single words, phrases, clauses, sentences, etc.) as well as the linguistic constraints that govern their appearance. Although there is still considerable controversy over this latter aspect (are constraints universal or language specific? how broad can a constraint be?)

it is now clear that switching is not simply a haphazard behavior due to some form of 'semilingualism' (see *Semilingualism*) but that it is, instead, a well-governed process used as a communicative strategy to convey linguistic and social information.

The other way bilinguals can bring in the other, less activated, language is to borrow a word or short expression from that language and to adapt it morphologically (and often phonologically) into the base language (see *Borrowing*). Thus, unlike code-switching which is the juxtaposition of two languages, borrowing is the integration of one language into another. Most often both the form and the content of a word are borrowed (to produce what has been called a loanword or more simply a borrowing) as in the following examples taken from French–English bilinguals: '*Ca m'étonnerait qu'on ait code-switché autant que ça*' (I can't believe we code-switched as often as that) and '*Maman, tu peux me tier/*taje/*mes chassures?*' (Mummy, can you tie my shoes?). In these examples, the English words 'code-switch' and 'tie' have been brought in and integrated into the French sentence. A second type of borrowing, called a loanshift, consists in either taking a word in the base language and extending its meaning to correspond to that of a word in the other language, or rearranging words in the base language along a pattern provided by the other language and thus creating a new meaning. An example of the first kind of loanshift would be the use of *humoroso* by Portuguese–Americans to mean 'humorous' when the original meaning is 'capricious.' An example of the second kind is the use of idiomatic expressions that are translated literally from the other language, such as '*I put myself to think about it*' said by a Spanish–English bilingual, based on '*Me puse a pensarlo.*' It is important to distinguish idiosyncratic loans (also called 'speech borrowings' or 'nonce borrowings') from words which have become part of a language community's vocabulary and which monolinguals also use (called 'language borrowings' or 'established loans'). Thus, in the following text, every third or fourth word is an established loan from French which has now become part of the English language: '*The poet lived in the duke's manor. That day, he painted, played music and wrote poems with his companions.*' Research in the late twentieth century has examined, among other things, the differences and similarities that exist between code-switches and borrowings (and within the latter, between idiosyncratic borrowings and established borrowings), as well as the impact of the two on language itself, such as first- and second-language restructuring.

3. The Psycholinguistics of Bilingualism

The psycholinguistics of bilingualism studies the processes involved in the production, perception, comprehension, and memorization of the bilingual's

13

languages (spoken, written, or signed) when used in a monolingual or a bilingual language mode. The emphasis has, until the early 1990s been put on the independence of the bilingual's languages (how does the bilingual keep the two languages separate? does the bilingual have one or two lexicons?) to the detriment of issues such as the on-line processing of language, be it in a monolingual or in a bilingual language mode. Much research was conducted, for example, on the coordinate–compound–subordinate distinction. According to it, there are three types of bilinguals: coordinate bilinguals who have two sets of meaning units and two modes of expression, one for each language (this means that the words of the two languages are totally separate entities); compound bilinguals who have one set of meaning units and two modes of expression ('equivalent' words in different languages have the same meaning); and subordinate bilinguals who have the meaning units of the first language and two modes of expression: that of the first language and that of the second, learned by means of the first (here the bilingual interprets words of the weaker language through the words of the stronger language). Despite the inherent appeal of this distinction, no amount of experimentation has brought conclusive evidence that bilinguals can be classified as coordinate, compound, or subordinate.

Another area of considerable investigation has been whether bilinguals possess one or two internal lexicons. Proponents of the one-lexicon view (also referred to as interdependent storage) state that linguistic information is stored in a single semantic system. Words from both languages are organized in one large lexicon, but each word is 'tagged' to indicate the language it belongs to. Other researchers have claimed that bilinguals have two lexicons (the independent storage view), and that the information acquired in one language is available in the other only through a translation process. Again, despite a large number of studies, no clear-cut results have been found. In fact, it has been proposed that bilinguals have *three* stores, one conceptual store corresponding to the bilingual's knowledge of the world and two language stores, one for each language.

A third issue of interest has been the ability of bilinguals to keep their two languages separate in the monolingual mode. Researchers have postulated the existence of a language switch which allows bilinguals to block out the other language, and experimental studies have been conducted to find evidence for this proposal. The results obtained have been inconclusive or, at the very least, questionable, and currently it is felt that no switch, be it psycholinguistic or neurolinguistic, exists in bilinguals. Rather, it has been proposed that bilinguals are probably using various activation and deactivation procedures to keep their languages separate in the monolingual

mode and to make them interact in the bilingual mode.

It is more generally accepted in the early twenty-first century that the bilingual is not two monolinguals in one person, but a unique speaker–hearer using one language, the other language, or both together depending on the interlocutor, situation, topic, etc. (see above). Current psycholinguistic research is trying to understand the processing of language in the bilingual's different language modes. Researchers are studying how bilinguals in the monolingual mode differ from monolinguals in terms of perception and production processes, and they are investigating the actual interaction of the two languages during processing in the bilingual mode. This latter issue has produced some interesting findings. For example, in the recognition of 'guest' words (borrowings and code-switches) the phonotactics of the word (whether it is marked clearly as belonging to one or the other lexicon), the presence or absence of a base language homophone, the language phonetics of the word (the pronunciation of the guest word in one language or in the other), and the language that precedes the word (the base language context), all play a role in the recognition process. Actual models of bilingual processing are now being proposed to account for the data obtained. Thus, an interactive activation model appears to accommodate the word recognition results just presented. In the production domain, researchers are attempting to explain the underlying processes involved in the on-line production of code-switches and borrowings and a number of models are also being proposed.

4. The Neurolinguistics of Bilingualism

Neurolinguists have long been interested in describing how language is organized in the 'bilingual brain' and how this organization differs from that of the monolingual. One approach has been to observe and test bilingual aphasics in order to better understand which languages have been affected by brain injury and which factors best account for the different patterns of recovery of the languages. Another approach has been to study normal bilinguals to ascertain whether language processing occurs mainly in the left hemisphere of the brain (as it appears to do in monolinguals) or in both hemispheres.

As concerns aphasia, researchers have observed various recovery patterns of the bilingual's two or more languages after injury (they have been labeled parallel, differential, successive, antagonistic, selective, mixed) and they have tried to account for the factors that seem to play a role in non-parallel recovery (that is, when the languages are not all recovered together at the same rate). Currently, no single factor has emerged to explain the different

types of recovery patterns, and it is not known whether recovery significantly differs following therapy in one language, in the other or in both. It would appear, though, that if a language is not recovered, it is not that it is lost, but simply that it is inhibited, temporarily or permanently.

On the topic of language lateralization, it is now a well-known fact that the left hemisphere of the brain in monolinguals is dominant for language. The question has been whether bilinguals also show strong left-hemisphere dominance for language. Until a few years ago, and based on case studies of bilingual aphasics and on experimental results, some researchers proposed that bilinguals use the right hemisphere in language processing more than monolinguals. However, after further studies that were better controlled, there appears to be clear evidence that monolinguals and bilinguals do not differ at all in hemispheric involvement during language processing. As concerns language organization in the bilingual brain, most researchers agree that the bilingual's languages are not stored in completely different locations. In addition, it would appear that bilinguals have two subsets of neural connections, one for each language (each can be activated or inhibited independently) while at the same time possessing one larger set from which they are able to draw elements of either language at any time. This said, the bilingual brain is still very much terra incognita, and only further experimental and clinical research will tell how similar it is to the monolingual brain and in what ways it may be different.

5. The Bilingual Person

This last section will discuss the attitudes and feelings bilingual and monolinguals have towards bilingualism, various mental activities in bilinguals, the interaction of language and emotion, and the personality of bilinguals.

5.1 Attitudes and Feelings about Bilingualism

It would appear from various surveys that have been conducted that either bilinguals have no strong feelings about their bilingualism (it is simply a fact of life!) or that they see more advantages than inconveniences in having to live with two (or more) languages. Most appreciate being able to communicate with people from different linguistic and cultural backgrounds, others feel that bilingualism gives them a different perspective on life, that it fosters open-mindedness, allows one to read and often write in a different language, makes learning other languages easier, gives more job opportunities, etc. As for inconveniences, these are less numerous and involve such aspects as mixing languages involuntarily, having to adjust to different cultures, feeling one is losing one of the languages one

possesses (usually a minority language) or having to act as a translator on various occasions. It is interesting to compare these reactions to the attitudes and feelings that monolinguals have towards bilingualism. These are extremely varied, ranging from very positive attitudes (such as wonder at the fact that some bilinguals can speak and write two or more languages fluently) to very negative attitudes (such as surprise that many bilinguals do not master their two languages perfectly, that they cannot translate automatically from one language to another, etc.). It should be noted that most of the views that monolinguals have about bilinguals are usually based on socioeconomic and cultural bilinguals are usually based on socioeconomic and cultural considerations rather than on linguistic factors.

5.2 Mental Activities, Emotion, and Stress

Little is known about the languages used by bilinguals in their mental activities or how bilinguals react when under stress or in an emotional situation. It does seem to be the case that many mental operations are language specific. Thus, bilinguals usually count and pray in the language in which they learned these behaviors. Thinking or dreaming also seem to be language specific and depend on the person, the situation, and the topic involved (see above). When tired, angry, or excited, bilinguals will often revert back to their mother tongue or to whatever language they usually express their emotions in. Stress may also cause more interference, problems in finding the appropriate words, and unintentional switching. In addition, it has been reported that bilinguals wish that the monolinguals closest to them (spouse, companion, friends) were also bilingual.

5.3 Personality and Bilingualism

Some bilinguals report that when they change language they change attitudes and behaviors. This has been alluded to quite frequently in the literature: some bilinguals seem to hold slightly different views depending on the language they are speaking; some others are more authoritarian in one of their languages; others still are more reserved or gentle, etc. Is it possible to conclude from this that there is some truth to the Czech proverb, 'Learn a new language and get a new soul?' (see *Sapir–Whorf Hypothesis*) Some would answer in the affirmative and go as far as to say that the bilingual has a split personality. In fact, there appears to be no real evidence that bilinguals suffer any more from mental disorders than monolinguals. In fact, what is seen as a change in personality is simply a shift in attitudes and behaviors corresponding to a shift in situation or context, independent of language. As was seen above, bilinguals will choose a language according to the situation, the interlocutor, the topic, and the intent of

15

the conversations. These factors trigger different attitudes, impressions, and behaviors (just as they do in monolinguals who modify the content and form of their discourse depending on the context), and thus what is seen as a personality change due to language shift may really be a shift in the situation and interlocutor. In a word, it is the environment as a whole that causes the bilingual to change languages, along with attitudes, feelings, and behaviors—and not language as such. The main difference between monolinguals and bilinguals in this respect is that bilinguals often shift languages (and hence appear to be different people) whereas monolinguals do not. In addition, bilinguals are often switching from one culture to another in their interactions (many are bicultural) whereas monolinguals usually remain within the same culture.

6. Research in the Twenty-first Century

Despite what is already known about the bilingual individual, much more research needs to be conducted on the topic. The emergence of a holistic view of bilingualism is encouraging researchers to move away from the monolingual yardstick and develop a true linguistics of bilingualism. However, many issues require further study: the structure and organization of the bilingual's different languages; the various processing operations involved in the perception, production, and memorization of language when the bilingual is in the monolingual or the bilingual language modes; the linguistic and psycholinguistic differences (and similarities) between code-switches, borrowings and interferences; the organization of the bilingual brain; and finally, the psychology of the bilingual and bicultural person.

Bilingualism, Societal

M. H. A. Blanc

Societal bilingualism or multilingualism refers to the co-existence of two or more languages used by individuals and groups in society. It should be distinguished from the contact of different languages within the individual, which is sometimes called bilinguality, defined as 'the psychological state of the individual who has access to more than one linguistic code as a means of communication' (Hamers and Blanc 2000) and is outside the scope of this article (see *Bilingualism, Individual*). Societal bilingualism does not necessarily imply that all members of the society are bilingual. In fact, paradoxically, a majority of the members of an officially multilingual country may be monolingual, because the different language groups are territorially separated by more or less fixed and secure boundaries, as is the case in Belgium and Switzerland (territorial bilingualism). Societal bilingualism is a widespread phenomenon, the vast majority of nation-states in the world having more than one language used indigenously within their borders; indeed, this must be the case since the total number of languages has been estimated at around 5000, while there are only some 200 states. The impression that unilingual states are the norm comes from the nineteenth-century concept of 'one nation-one language' and from confusion between

language and official language, confusion perpetuated by geolinguistic maps. Moreover, language and state are not necessarily coterminous: the same language may be spoken in several different countries. For example, English and French are official in countries the world over, whether spoken as a first or a second language, by majorities or minorities. German is the majority official language in Germany and Austria, one of the official languages of Luxembourg and Switzerland, and spoken as a language or dialect by minorities in Belgium, Czechoslovakia, Denmark, France, Hungary, Italy, Poland, Romania, and Russia, to name only European countries.

1. Origins of Societal Bilingualism

Societal bilingualism develops from a variety of contact, both between and within countries and communities. It is found in border areas between states, either because of constant interchange through visits, trade, work or wars, or because a geographical dialect continuum has been interrupted by more or less arbitrary political frontiers. One example is the West Romance language continuum in Europe, which cuts across the national borders of Portugal, Spain, France, Belgium, Luxembourg, Switzerland, and Italy. Although the standard varieties of Portuguese, Spanish, French, and Italian are mutually unintelligible, the rural dialects of these languages are linked by a chain of mutual intelligibility, such that speakers on either side of the political borders have few problems understanding each other. Moreover, these people are bilingual, since they speak the official national language as well as the regional or local language/dialect. For example, many Galicians in northwest Spain speak Gallego (a variety of Portuguese) and Castilian; a majority of Catalans speak Catalan and Castilian. In the Valle d'Aosta many Italians speak French as well as Italian, while a majority also speak a Franco-Provençal dialect which has recently received some official status. Political events may divide people speaking the same language or bring together people speaking different languages. The first pertains in many African and Asian countries previously under colonial rule, where the colonial powers drew arbitrary frontiers regardless of ethnolinguistic realities. Conversely, alloglots may be brought together, whether voluntarily or by force. In the former case, we have free federations, like Switzerland or the European Community; in the latter case we have more or less enforced federations, like the former USSR or the former Yugoslavia. Annexations and invasions, migrations and mass deportations also bring groups from different cultural and linguistic backgrounds together, as can be seen by the many shifts of borders in Central and Eastern Europe in the nineteenth and twentieth centuries, with resulting new language contacts and conflicts. Economic factors can also bring alloglots into contact, whether voluntarily (e.g., the European Community) or from necessity (e.g., immigrants to North America) or by force (e.g., the slave trade). Religion can be a reason for different linguistic groups who share the same faith to live together, whether temporarily (e.g., pilgrimages) or permanently (e.g., the Indian subcontinent, Israel). Conversely, different religious groups may divide a country along linguistic and religious lines. For example, at the time of partition in 1947 the Indian subcontinent split up along religious lines, thereby dividing a common lingua franca, Hindustani, into two distinct official languages, Hindi used by the Hindu community, and Urdu used by the Muslim community. Lastly, a society may decide to make a second language official alongside the indigenous official language in order to gain access to wider markets or information. An example is the increasing use of English as an official or semi-official language in many countries of the world, and its use as an international auxiliary language. But whatever the reasons for societal bilingualism, it always involves languages in intergroup relations.

2. Sociolinguistic Variations in Language Contact Situations

In a situation of societal bilingualism the status of each of the languages in contact varies as a function of, on the one hand, intergroup power relations and, on the other hand, the perception that speakers form of these relations. When intergroup relations change, status relations and perceptions, attitudes and uses also change. It is important to stress that it is not so much the languages that vary as their speakers, who select from a variety of possible models, which are socially marked. As Le Page points out, change only takes place when the social values attached to the models change and the behavior of the speech community also changes (Le Page and Tabouret-Keller 1985) (see *Identity and Language*).

2.1 Speech Repertoires in Multilingual Communities

In a multilingual speech community a whole range, or repertoire, of languages is available to speakers, who use some of them in their linguistic interactions to perform particular social roles. Note that the term *repertoire* is also used to refer to the range of language varieties, such as dialects, registers, and styles typical of a unilingual community of speakers for whom the choice of one variety rather than another can have the same social value as code selection in a multilingual community (Gumperz 1971). Repertoire applies to both the speech community and the individual. No bilingual speaker controls the whole range of codes that constitute a speech community's repertoire continuum but only a

17

number of these (his verbal repertoire). An illustration of a complex multilingual repertoire is that provided by Juillard (1995) who has investigated the urban area of Zinguinchor in West Africa, situated at the cross-roads of three states: Senegal (official languages: Wolof and French), Gambia (English) and Guinea-Bissau (Portuguese), and of numerous ethnic groups and languages: eight African, three ex-colonial, and one creole. Speakers in Zinguinchor classify their repertoire in three ways: languages of identity, of cross-communication, and of culture. In the wider educational domain, boys use French, girls use Wolof. Speakers vary from a trilingual farmer who uses Diola (the majority language) and Mandinka with men and Wolof with his mother and sister, to a high school boy who declared speaking 20 languages and used eight daily. In the market place Peul (Kpelle) is the language of transactions, Wolof the language of bargaining power, and French is used to conclude a bargain. An example of how a multilingual speaker uses the different codes in his repertoire is that of an Indian businessman dealing in spices and living in the suburb of Bombay described by Pandit (1979). His mother tongue and home language is Kathiawari, a dialect of Gujarati; he reads his daily newspaper in standard Gujarati; in the market place he uses a colloquial variety of Marathi, the state language; at the railway station he speaks Hindustani, the pan-Indian lingua franca; the language of business is Kachchi; in the evening he will relax watching a TV film in Hindi or English, or listening to a cricket-match commentary in English. (For a typology of speech/verbal repertoire, see Kachru 1982.)

What roles does each of the different languages play in a speech community? These various codes are neither used nor valued in the same way: if they were, all but one would become redundant. They usually fulfill different functions in the sense that each is used according to interlocutor, domain, topic, and role, the choice of one code involving an 'act of identity' (Le Page and Tabouret-Keller 1985) on the part of the speaker (see *Identity and Language*; *Role Theory*).

2.2 Diglossic Bilingualism

When two or more different varieties or languages co-occur throughout a speech community, each with a distinct range of social functions in complementary distribution, we have a situation of diglossia (see *Diglossia*). Originally developed by Ferguson (1959) to describe two functionally different varieties of the same language, one called the high variety (H), reserved for formal uses and formally learned, the other the low variety (L), used in informal situations (example of diglossia: classical (H) and colloquial (L) Arabic). The concept of diglossia has been extended to cover multilingual situations. Examples of diglossic bilingualism range from simple binary contexts,

e.g., Guaraní (L) and Spanish (H) in Paraguay, to double-overlapping diglossia, e.g., African vernacular (L), Swahili (L and H) and English (H) in Tanzania (the last two are second languages), or double-nested diglossia, with L and H having each an L and an H variety, e.g., Khalapur in North India, to linear polyglossic situations characteristic of Singapore and Malaysia (see *Diglossia*).

One of the most complex polyglossic situations is found in Northern India (Khubchandani 1979). At the local level dialects vary from village to village to such an extent that they quickly become mutually unintelligible: when a villager visits a neighboring town he must use a less localized variety in order to be understood. This is how local trade languages developed and became regional dialects. Above them is one of the official state languages. Each state language comprises a colloquial and a standard form. Over and above these are the two official national languages, Hindi and English. Hindi is also a regional language extending over several states and diversified into a number of dialects. The Hindi-Urdu-Panjabi geolinguistic area of Northern India comprises 46 percent of the total Indian population and is a vast polyglossic continuum where languages and dialects complement, or merge or compete with one another according to domains, functions, social group, and religious affiliations.

Diglossia does not remain stable but evolves and changes. It is said to 'leak' when one language/variety invades the domains and functions previously reserved for the other: this is a sign of an incipient breakdown in the diglossic relationship which reflects changes in power relations between the groups in the society. The result is either a blend of the two former H and L varieties or a language shift.

2.3 Language Shift

When members of an ethnolinguistic group start using the language of another for domains and functions hitherto the preserve of their own language (L1), the process of language shift is under way. Typically, language shift takes place over three generations: the first is either unilingual or dominant in L1; the second is variably bilingual (L1/L2); the third dominant or unilingual in L2. The shift also takes place in synchrony: at a given point in time the first generation is still monolingual in L1 while the last is already monolingual in L2. Throughout this process L1 is affected by L2; its forms and uses are reduced; its speakers borrow heavily from it, mixing, and switching between, the two codes (see de Bot and Clyne 1994). In extreme cases a group's language may cease to be spoken at all: this is an example of language death. A number of factors account for language shift, the most important being changes in the way of life of a group, which weaken the strength of its social networks (e.g., urbanization, education);

changes in the power relations between the groups; negative attitudes towards the stigmatized minority language and culture; or a combination of all these. Language shift has been studied from various perspectives: sociological and demographic at the macro-level (see, for example, Tabouret-Keller 1968); social psychological (see Landry et al. 1996); and ethnographic at the micro-level (see, for example, Gal 1979 and Kulick 1992), each approach using specific research methods which are complementary. Language shift and language death adversely affect the state of societal bilingualism in the world and should be better understood if languages and cultures in pluralist societies are to be maintained (Fishman 1991) (see *Language Maintenance, Shift, and Death*).

2.4 Lingua Francas, Pidgins, and Creoles

In language shift one language is abandoned for another and may die. But there is a situation in which a new language is born out of languages in contact: this process is known as pidginization. When speakers with different mother tongues want to communicate with each other they use a lingua franca when one is available; it is a natural contact language, like, for example, a trade language (e.g., Hausa in West Africa, Swahili in East Africa). A pidgin is a contact language, which has no native speakers and is the product of a multilingual situation in which people must develop a new language to be able to communicate. One distinguishes between endogenous pidgins, which are born from the contact of a native population with foreign traders, and exogenous pidgins which develop from contact between non-indigenous populations speaking mutually unintelligible languages, as in the case of slaves or indentured laborers on the plantations and their masters. Typically, a pidgin evolves out of low-status substrate languages spoken as L1s (e.g., the African languages of slaves) in contact with a high-status superstrate, or base language (e.g., English, French, Dutch, or Portuguese). A pidgin is an L2, which results from an incomplete learning of the superstrate owing to a quantitatively and qualitatively restricted input. It is a mixed language, which borrows from both substrates and superstrate: the forms of the lexical items are derived from the latter, while the syntactic and semantic properties of these lexical items follow the rules of the former (see, for example, Mühlhäusler 1986).

When a pidgin has to fulfill new, more numerous and complex social functions, it develops new and complex forms and structures, until adults begin to use it as the main language of communication and children learn it as their mother tongue (nativization process): the pidgin has become a creole, which is a relatively stable language, though in constant interaction with the base language (see, for example, Jourdan and Keesing 1994). Sometimes, because of economic, social and cultural pressures, the creole evolves in the direction of the base language by a process called decreolization (Bickerton 1975). Pidgins and creoles are real languages, suited to the needs for which they are developed. Some even become official national languages, like Tok Pisin in Papua New Guinea. Their study enables linguists to witness their birth and development; their variety and relative speed of transformation provide new insights into language change and behavior (see also *Lingua Franca*).

2.5 Theoretical Implications of Societal Bilingualism

When different linguistic groups come into contact their languages come into contact. These languages may either converge or diverge, or converge and diverge at one and the same time. This is because the degree of variation in intra- and inter-lingual uses depends on the relative strength of two tendencies in society: the tendency to reduce intergroup differences (convergence) and the tendency to accentuate these differences (divergence). Convergence is found where speakers are in close and constant contact and there is consensus on the norms of language behavior; it characterizes small communities with dense and multiplex social networks (see *Social Networks*) as well as societies where a standard written language is imposed as the legitimate norm on a nation or group of nations (e.g., French, English and Classical Arabic, as national and international languages). Divergence, on the other hand, prevails in situations where there are no imposed norms and social networks are loose, leading to wide variations in usage. Language creativity is then at its highest, as in pidginization. Sometimes both convergence and divergence are at work, as the following examples show.

The 3000 inhabitants of Kupwar in South India between them speak four different languages, Marathi and Urdu (both Indo-European), Kannada and Telugu (both Dravidian). The village is divided into clearly distinct castes, each identified by its language. As they need to communicate, they, especially the men, learn each other's languages. Over centuries their syntaxes have converged and become more similar than they are in other parts of the Indian subcontinent (the convergence is essentially towards Marathi, the state language). However, they are still distinct in their respective vocabularies, which serve as a powerful symbol of each group's ethnic identity and distinctiveness (Gumperz and Wilson 1971).

In Nairobi, Kenya, at a time of great social change, children from four different ethnic and language backgrounds speak Swahili in the streets but, as adolescents they divide into two camps, each one identifying with either Swahili or English, each symbolizng their different social allegiances. As adults, however, they return to their original

19

ethnolinguistic groups through endogamy, but all also use Swahili, while some are capable of speaking English. Here there are successively acts of convergence and divergence expressed by allegiance to different groups and languages at different times (Parkin 1977).

Mixed languages are in-group languages, usually with their grammatical structure taken from one language and their lexicon from another, e.g., Maltese (Arabic with heavy borrowings from Italian and English) or Media Lengua (Quechua and Spanish). A very unusual mixed language is Michif in Western Canada and North Dakota (Bakker 1994). The internal structure (phonology, lexis, morphology, and syntax) of the noun group is essentially French (dialect), while that of the verb group is essentially Cree (an Algonquian language). Is Michif a case of code switching? The answer must be no, since in code-switching speakers are more or less competent in the two languages and most Michif users speak neither French nor Cree. Is it a pidgin? But Michif is the mother tongue of its speakers and is a fully developed language. Then is it a creole? In so far as a creole is a development from a pidgin, then Michif is not a creole. Moreover, Michif is an in-group language, while creoles are developed for communication across languages. Thus Michif poses a real puzzle for linguistic theory: what is its syntax? What do categorial rules look like, since French and Cree have very different rule systems? How should its lexis be organized? Are there one or two phonologies? These are some of the theoretical questions which linguists have to answer (see *Intertwined Languages*).

Thus, variation and change are the essence of language, because language is at once the expression, symbol, and instrument of a group's identity and of its dynamic relations to other groups in a society. A language is not a homogeneous, static entity; it varies along multidimensional continua and its speakers identify with some of the varieties and their verbal repertoire is an expression of these identities.

3. Language Planning in Multilingual Societies

Confronted with many different languages within its boundaries, how does a state solve its communication problems, given the complexity of ethnolinguistic group relations? Historically, the state has imposed one language, usually the dominant legitimized language of the ruling group, upon the other linguistic groups, thus either reducing the latter's languages to minority status or eradicating them by assimilating its speakers through education or coercion. For example, the French State, in its pursuit of national unity, has succeeded in imposing the Parisian sociolect on the whole of its population at home and on the elites of its colonies overseas, thus

making French the official language of the French-speaking world (francophonie).

Today, however, the state uses the much subtler instrument of language planning, which is a species of economic planning (Grin 1996). Language planning is of two kinds, internal (or corpus planning) and external (or status planning). Corpus planning, a form of linguistic engineering, is the same in multilingual as in unilingual societies. Status-planning means interfering with the existing status relations between the languages and their speakers and using one or more languages for official purposes. As the status of languages is a function of the relative economic, demographic, social, cultural and political power of the various linguistic groups and of the subjective perceptions of these power relations, status planning will necessarily reflect the power structure in society (Fishman 1994). Two main approaches confront each other: nationism and nationalism (Fishman 1968). In the nationist solution a language is selected for reasons of national efficiency (e.g., English and French as official languages in most former British and French colonies). In the nationalist solution language acts as a powerful symbol and instrument of ethnic identification, and the different ethnolinguistic groups resist acculturation by maintaining or reinforcing their language (e.g., Catalan in Spain, Flemish in Belgium, French in Canada). But most cases in the world fall between these two solutions, especially in multilingual states. Usually, one or more regional languages are given national status together with a national or international language. A comparison between Singapore and Malaysia will illustrate the difference between the nationist and the nationalist option.

Both Singapore and Malaysia are multiethnic, multireligious, and multilingual societies. It is noteworthy that, while these states have evolved along similar historical lines and are composed of roughly the same ethnic mix—though in different proportions—they have chosen very different approaches to language planning. Malaysia has opted for a nationist (or 'depluralization') solution: divided along geographic, political, linguistic, ethnic, religious, and economic lines, it has followed the path of cultural assimilation with the adoption of Bahasa Malaysia (Malay) as the sole official language of the country. In Singapore, by contrast, the traditional cultural values of each major group have been fostered, a policy of cultural integration (as opposed to assimilation) has been pursued, and the four main languages (Malay, Mandarin, Tamil, and English) have been made official. But this policy is not one of strict nationalism, since, while encouraging the three ethnic languages as a foundation for the maintenance of traditional values, it has at the same time emphasized the functional importance of English as

the basis for a supra-ethnic Singaporean identity (Ward and Hewstone 1985).

One of the key issues in language planning, particularly in the West, is that between the personal and the territorial solution to the problems of the multilingual state. The personal solution is based on enforcing individual rights throughout the state; these include the right to understand and be understood in public life, to be educated in one's own language, and the right to one's own identity. By contrast, the territorial solution consists of separating the different language populations by fixed boundaries. There are several models of territoriality, of which the Swiss, the Belgian, and the Canadian are examples: all show tensions between the territorial and the personal solution. In the former Soviet Union the dominant Russian group used the territorial solution on the one hand to protect minorities and, on the other, to protect and promote its own interests. All the republics, with the exception of the Russian Federation, were officially bilingual, Russian being in every case one of the official languages. Russian-speaking minorities had the right to use their mother tongue, while the other ethno-linguistic groups had to learn Russian as well as their own language. But in the Russian Federation only Russian was official. The principle of territoriality led to an asymmetrical, non-reciprocal bilingualism (see *Language Planning: Models*).

A presumed link has been suggested between multilingual societies and national underdevelopment: does the fact that a country is culturally and linguistically diverse and heterogeneous cause that country to be economically disadvantaged? Are nation-states more stable than multinational ones? Pool (1969) tried to show that linguistically diverse countries tend to be underdeveloped, while highly developed countries have considerable linguistic uniformity. However, other researchers have challenged Pool's methodology and findings; they argue that both linguistic diversity and economic disadvantage are the legacy of colonialism (Liberson and Hansen 1974). Moreover, are not some of the most advanced and dynamic countries and cities in the world, such as the US, Canada, Australia, Hong Kong and Singapore, among the most ethnically and linguistically heterogeneous? As Weinreich pointed out as long ago as 1953, the greater the linguistic diversity of a country, the greater the degree of bilinguality and bilingualism. Where there are many people who speak many different languages, they will learn each other's languages. In other words, individual and societal bilingualism compensates for linguistic diversity (see *Language Development*).

4. Education in Multilingual Societies

Education is one of the tools of language planning. One of the most intractable yet urgent problems of language planning worldwide is that of ensuring at least functional literacy, that is, a level of literacy that will enable people to function in a given society. This is not so much a technical as a social issue, since illiteracy is an obstacle to informed citizen participation in decision-making and to national development. Illiteracy is a problem not only for the Third World but also for developed post-industrial countries, which have recently known a sharp rise in illiteracy rates, owing to the marginalization of immigrant communities and the rise of unemployment. Unfortunately, both status and corpus language planning are not adequate instruments for tackling these wider social issues. The limited success of large-scale state measures would suggest that small-scale solutions with multiple literacy programs at all levels are preferable (Tabouret-Keller et al. 1997).

What of bilingual education and the teaching of the mother tongue to linguistic minority children? Two important contextual aspects in the development of these children must be borne in mind: firstly, they usually come from a devalued linguistic background and, secondly, because they often come from socially deprived communities, their literacy-oriented skills are less developed than those of the children from the dominant language group. They suffer from a double handicap when they are schooled with the children of this latter group: they have to develop literacy skills in a language they either do not know, or only know for communicative purposes, and cannot fall back on their first language for literacy functions. The poor academic achievement of these children is then attributed by the educational system to a cognitive deficit. Cummins (1984) has given a critical review of the use made of academic assessment tests to demonstrate the deficit of minority schoolchildren. He shows that there is strong experimental evidence that valorizing the first culture of these children and introducing literacy skills in their first language enhance both linguistic and academic achievement. Experiments in bilingual education, that is, where the first and the second language are used as media of instruction demonstrate how the subtractive situation in which minority schoolchildren find themselves can be turned into an additive bilinguality. By valuing the first language and culture of these children, and motivating them to learn through their mother tongue, their linguistic and cognitive abilities are enhanced (Hamers and Blanc 2000) (see *Cummins, Jim*).

Unfortunately, the majority of bilingual programs for linguistic minority children are transitional ones, which have been decided by the dominant group. The ultimate aim is the assimilation of the subordinate groups who will, in the long run, be at best dominant, at worst monolingual, in the second language, and be acculturated or assimilated. So, even if bilingual education appears to be a necessary condition for the

maintenance of minority cultures and languages and the academic achievements of minority children, it is not a sufficient one. Only a strong ethnolinguistic vitality, allegiance to the cultural group, and the use of the mother tongue in the home and the speech community will ensure cultural and linguistic survival (see *Ethnolinguistic Vitality*). For of all the domains it is the family network that most resists the penetration of the dominant language and perpetuates societal bilingualism.

Communication

K. L. Berge

The content and use of the term 'communication' is even by humanistic standards extremely ambiguous, and it has therefore often been difficult to use in practical, empirical work. The most exact use of the term has been standardized in Shannon and Weaver's information theory. Within the tradition of semiotics,

the value of communication as a term has been questioned, and in linguistics the term has sometimes been used as a synonym or part-synonym with more exactly defined terms such as use, parole, text, behavior, and performance. In spite of this, certain theorists—often those with a background in cybernetics—have used 'communication' as a generic term for all theories about man, in the same way as semioticians have defined the domain of semiotics.

A very simple and general, but neither unproblematic nor uncontroversial, way of defining communication is to view it as an information process going on between at least two human communicators (not necessarily two persons as long as one can communicate with oneself) embedded in a context (see *Context*), and a situation. More specifically, communication can be defined as a generic term covering all messages uttered in different contexts and situations.

A message can be divided into sign-vehicle and meaning. The sign-vehicle then covers all possible variants on the expression plane of linguistic utterances, and meaning covers all possible variants on what is called, in the glossematic school, the content plane. In this way, communication is used as a sociological term, and language is viewed as a primarily social fact (see *Sociology of Language*).

Furthermore, communication can also be conceived of as inherent in the linguistic message. The situation, the context, and the communicators involved in communication make their mark on the content and expression planes of the message. This definition is neutral with regard to the different traditions in linguistics which divide language for instance into 'langue' or 'system' on the one hand, and 'parole' or 'behavior' on the other (see *Saussurean Tradition and Sociolinguistics*).

1. 'Communication': Different Models and Metaphors

One possible way of bringing order into the rather chaotic world of the different approaches to the study of communication in linguistics, is to differentiate between the various trends in communication-relevant research. These trends can be classified according to the basic models of communication they have adopted. Or rather, according to the different metaphors that linguists use in order to try to illustrate or make explicit the phenomenon of communication.

1.1 The Linear, Conduit Model

The simplest model of communication has been called the conduit model (Reddy 1979) because of its underlying assumption that language functions as a sort of channel, or tool for transferring a linguistic message from a source (or sender) to a destination (or hearer). This idea of communication has some of its roots in information theory. To separate what they call information from communication, certain philosophers of language (e.g., Grice) have advocated the idea that communication proper is characterized by intentional communication, or what Grice calls 'non-natural meaning'. The idea is that the addresser ('sender') intends that the message (or utterance) will cause what is called an effect in the addressee ('receiver'). The only necessary condition is that the addressee recognize this intention. In spite of the differences between these approaches, they are basically teleological models of communication, and this makes them closely related to perhaps the oldest theory of communication, namely that of classical rhetoric. Rhetoric can be defined as a theory of communication that seeks to find the quality which makes it possible for an addresser to persuade or convince his addressee about something.

The most problematic aspects in these models are the notion of effect, or perlocution on the addressee's side, and the notion of intention on the addresser's side. How are we to build a theory of communication on such vague terms, and how are we to find out what is/was the intention in a message and how are we to distinguish between the different effects? Other problematic aspects are the basically individualistic and monological views of communication that advocates of such models implicitly accept. Such views are seriously challenged in the three following communication models.

1.2 The Circular, Dialogic Model

The basic idea in what is here called the circular or dialogic model (see *Dialogism*), is that for communication to take place, it is not sufficient that an addresser manifests his intention in a message which results in an effect in the addressee. It is also necessary to give the addressee a more active role in communication.

First, this active part is the more or less conscious interpretation process that the addressee must be involved in for the intended message to get through.

Second, a more or less expressed manifestation of the intended effect in the form of a response, answer, action, etc. from the addressee is necessary for the addresser to understand that his message has been received—in fact, *is* a message. Without a response of some sort, the addresser would be left in a situation where he is at best talking to himself, at worst is indulging in a monologue more typical of madness. Thus, the interpretation requirement is not restricted to the addressee alone. The addresser, too, has to identify some sort of signal in the addressee's message which can be interpreted as a response or reaction to the intended message.

In this way, communication can be seen as a system of questions and answers, or as a sort of cooperation where the communicators are actively organized in the construction of the message. It is not necessary that the addresser's intended meaning is

identically reproduced by the addressee. If such an interpretation is at all possible, it is certainly limited to extremely restricted contexts, e.g., when certain logicians communicate solely with the help of logical formulas. The prototypical communication between humans is in fact characterized by the opposite: a partial, or limited understanding, or even misunderstanding, on the part of the addressee, which has to be clarified by further messages. Communication is not only the transfer of intentions with language as its tool. It is a constructive process going on in time. The message is constructed through the mutual activity of the actors. In this way, communication is a creative dynamic process. In fact, if communication did not have these qualities, a great deal of quite normal linguistic activity, like small talk during a lunch break, would be meaningless.

What is retained in this model from the conduit communication model, is the notion of intention. For dialogue to take place, it is necessary that the communicators intend to take part in the conversation, that they accept some sort of honesty principle, etc. Such principles are described in theories of conversational implicatures or of pragmatic universals (see *Pragmatics and Sociolinguistics*).

1.3 The Feedback, Interaction Model

The third model of communication distinguishes itself from the dialogical model by doing away with the notion of intention altogether. In this model, communication is viewed in a much more general way than in the two previous ones. Communication would include all those processes by which human beings influence one another. In its most extreme form, this model entails that all behavior can be said to be communicative. The interaction of human beings is characterized by the necessity to communicate; this necessity is superior to the notion of intention, which is based not only on the will to communicate, but also the will to interpret. Communication is thus part of perception; attention to and interpretation of communication are part of the process of perceiving.

What remains in this model are the principles of mutuality and reciprocity as basic requirements for communication to take place. However, those principles are not governed by normatively colored principles, such as Grice's conversational implicatures and Habermas's universal pragmatic consensus principles. In those frameworks, communication is a certain mutual tuning which necessarily must involve a certain moral commitment, that one believes what one says to be true, that one intends that which one says, and that the addressee necessarily takes for granted that the addresser follows these and similar principles (see *Cooperative Principle*). Communication, in the feedback model, is not characterized by a search for what could be called mutual knowledge,

consensus, or intersubjective understanding. Rather, the opposite is the case, namely that to communicate is to experience such principles as ideal goals: one cannot share other people's experiences or mental worlds, or truly understand the intentions of other communicators. The reason is that these principles of general reciprocity and mutuality are subject to societal power relations (see *Power and Language*). Such relations are neither intended to be recognized in the message, nor perhaps even intended to be a part of the meaning of the message at all. But as sociologists insist on telling the naive linguist, power relations are inherent in every communicated message (see *Manipulation*). There is no society in existence without social hierarchies of some sort; a powerless utopia is at best a pastoral idyll, at worst a totalitarian goal.

The basic problem in the feedback model is how to distinguish communication from information. As long as neither the addresser's nor the addressee's intentions are preconditions to communication, how are we to discriminate between all the incoming information, both on the content and expression planes of a message—an amount of information which, according to certain theorists, is infinite? It seems that this problem can be solved only by defining communication as involving both information (in the sense of information theory), the conveyed message, and the understanding of the message. Advocates of this model focus on the temporal nature of communication; communication is viewed as an enduring process which imposes meaning upon disturbances and noise, through the selective processes of information, message conveyance and understanding. Such a selection process is, of course, determined by the internalized language of the communicators, and is governed by other semiotic systems as well.

1.4 The Self-regulatory (Autopoesis) Model

The autopoesis model appears to be a radicalized version of the feedback model, in the sense that the model seems to have done away with what have been called the principles of reciprocity and mutuality. The autopoesis model is therefore something as seemingly paradoxical as a solipsistic model of communication. In this model, the communicators (or as they are called, the 'emitters' and 'receivers') do not communicate in order to transfer and create a message (as in the conduit and dialogue models), or even to create some information, a conveyed message, and an understanding, but simply to integrate elements from the communicative situation (the environment) which can contribute to the communicators' so-called self-regulation and self-creation (hence the term 'autopoetic'). This self-regulation and self-creation is an individual, idiosyncratic version of an interaction input. A basic goal of this self-regulation or

autopoesis is to create a difference with respect to all other (real or potential) communicators. In this sense, communication is necessary for the individual in order to be constituted as an individual. The communicators are seen as closed systems, insofar as nothing can be integrated which is not specified in the system's own structure. It is important to note that the system is not a static structure, but rather a process. Communication is self-reflection, characterized as an unceasing search for functional substitutes.

Interestingly enough, this model allows for another, more advanced view of linguistic messages, such as written texts, than is normal in the linguistic tradition (see *Speech and Writing*). Instead of being viewed as inferior reproductions of the prototypical or even 'natural' linguistic communication, namely verbal conversation, written messages are viewed as more communicative and creative, in that they not only allow for a finer distinction between the individual communicator and his communicative environment, but also for more permanent self-referential and autopoetic activity on the part of the individual communicator. Oral dialogue is thus reduced to one type of communication among others.

2. The Relation Between Communication and 'Language'

So far, the fundamental problem of the relation between communication and language has not even been superficially touched upon. Language is what most linguists recognize as the one and only object of linguistics; however, its relation to communication is a matter of continuous controversy: in fact, it is not even clear that the phenomenon of communication is at all relevant for the study of languages, and of language as such (see Sect. 3, below).

Still, most linguists are willing to accept a division of the phenomenon of language. On the one hand, it is seen as a kind of stable, over-individual structure, or type-schema, which for the sake of simplicity may be called a 'signification system.' On the other hand, it can be viewed as a set of tokens somehow belonging to such a schema, these may be called 'utterances.' This opposition between a system of signification and its associated utterances has many names, e.g., langue–parole (Saussure), schema–usage (Hjelmslev), code–behavior (Halliday), competence–performance (Chomsky), to name just a few of the most influential. The status of communication varies depending on, first, which opposition one considers most relevant, and second, which element in the opposition one chooses as most fundamental for the study of language.

The latter alternative allows us to distinguish between what the Soviet philosopher of language V. N. Voloshinov (see *Voloshinov, Valentin Nikolavic*) called 'abstract objectivists' on the one hand, and on the other, a heterogeneous group (consisting of behaviorists, empiricists, nominalists, 'socio'-linguists, processualists; etc.) called 'skepticists.' These groups will be dealt with in the following.

2.1 The Abstract Objectivist View

The abstract objectivist view can, in the light of the history of modern linguistics, be considered the traditional way of seeing things. The prototypical abstract objectivist sees language as a relatively stable, finite, and invariant system of signification, that is either as a unifunctional, adult-type system which is the goal of socialization, or as a social institution (Saussure's 'langue'), or as a universal innate mental grammar (Chomsky's 'competence'), or even as a pure form (Hjelmslev's 'schema'). The relation between signification system and utterances is seen as an either–or opposition: either one studies language systematically (i.e., as a signification system), or one doesn't study it at all. In this view, language is then something which precedes communication.

It does this in two different ways: First, as a generic term for language utterances, and therefore as a synonym of performance, behavior, usage, and parole. Second, communication can be viewed as the context (see *Context*) where language is used between communicators uttering tokens belonging to the signification schema, i.e., the language system.

In both these views, language is seen as a precondition to communication, either as a structuring grammar of utterance tokens, or as a common code (see *Code, Sociolinguistic*) of some sort, defining the difference between what has meaning and what is meaningless. The code is necessary for communicators transferring a message, as in the conduit model (see above, Sect. 1.1), accomplishing a dialogue, as in the circular model (see Sect. 1.2), interacting with one another, as in the feed-back model (see Sect. 1.3), or reaching a state of autopoesis, as in the self-regulatory model (see Sect. 1.4).

2.2 The Skepticist View

Common to the skepticist view is the radical critique of the abstract objectivist opposition between the system of signification and the utterances derived from the system.

The skepticists challenge this opposition in three different and not necessarily compatible ways. In all three, communication plays a more important role in research and reflection on language than in the abstract objectivist tradition.

2.2.1 Language as Communicative Behavior

The skeptics' first option is to get rid of the opposition altogether. Language as a signification system is viewed as a mentalistic abstraction from a heterogeneous mass of data. This mentalistic abstraction is considered as type–schema product created by

the analyst. Language is, then, a generic term for communicative behavior. This view is typical of the nominalist and the radical descriptivist. A prominent group of philosophers of language embracing these ideas are the so-called 'analytic philosophers' in the Anglo–American tradition (e.g., the later Wittgenstein, Strawson, Grice, Quine, Goodman). Meaning of linguistic messages in communication can only be said to belong to a signification system as an arbitrary classification of intentional (or habitual) acts having some sort of common similarity, the so-called 'family concepts.' An abstract objectivist theory of meaning, such as the (Saussurean) structuralist theory of semantic components and fields is in principle impossible, since in any case, message meaning is determined by an infinite number of components in a steadily changing communication situation, where intention, contextual setting, contextual restriction and other situational components play a major role.

2.2.2 Communication as Determining Language

The second option turns the abstract objectivist view upside down. It claims that communication (as a set of messages, not utterances) precedes, and is a precondition of, the signification system, not the other way round. Communication is viewed as determining language. Language is a message structure (Rometveit) embedded in time, which at the same time structures, constructs, and creates meaning as the result of an ongoing dialogic process. This view of language is closely related to the circular communication model (see above, Sect. 1.2), but it can also be seen as related to the nonintentional search for a common code which makes communication work in the interaction model (see Sect. 1.3), and to the notion of consensual domains as a prerequisite for the process of communication in the autopoesis model (see Sect. 1.4).

Many linguists involved in a sociological description of language choose this option (see *Sociology of Language*; *Language as a Social Reality*). Approaching language from the corpus of messages, and not from a hypothetical, abstract system, one is struck by the heterogeneity of the data. Not only is communication a multidimensional semiotic, where verbal and written language play a subordinate role (as in phenomena of the 'double bind' type), but communicators may use different signification systems simultaneously, or even systematically break such systems' unconscious normative rules. This heterogeneity in communicative activity could be interpreted as a process of signification whose variation is an index of the conflicts between different, incompatible signification schemes.

An example of how such a linguistic heterogeneity and flexibility in verbal communication can be legalized as the norm of a national written language is furnished by the two standards of written Norwegian. These standards represent two languages, in fact two competing conceptions of what constitutes 'Norwegian.' Since these conceptions are socioculturally determined, the languages could be called written sociolects (see *Language in Society: Overview*). In each language, a great number of morphemic and lexemic variants are admitted. For instance, the following are all possible determiners of the singular substantive *bok* 'book': *bok-en, bok-a, bok-i* 'the book.' On the lexical level, variation is allowed, where other written languages normally would have only one lexeme. For instance, two variants for the lexeme 'language' are possible: *sprog, språk*. Morphological variants such as these have different social, political, stylistic, regional, etc., meanings dependent on context and genre; these different meanings are familiar to every relatively language-competent Norwegian. For a descriptive, synchronic grammar of written Norwegian which pretends to be exhaustive, it is thus necessary to allow for situational rules, sociological parameters, and the like. It is not in principle possible to reduce the morphemes *-en, -a, -i* to a single abstract archimorpheme, or the lexemes *sprog, språk* to one and only one invariant ideal. In fact, the history of written Norwegian at the beginning of the twenty-first century is characterized by a willingness on the part of the language planners to accept a great many variants, because of these variants' different meanings in different contexts and situations. Interestingly enough, this sociologically determined multidimensionality seems to be one of the crucial factors that explains why Norwegians generally are much better at understanding their closely related neighbors, the Swedes and the Danes (who use written codes of the more unifunctional type), than the other way round (see *Sociolinguistics and Language Change*).

2.2.3 Communication and Language as Complementary Phenomena

The third alternative to the abstract objectivist view of language and communication is to claim that the elements in the opposition are complementary to each other. Language is *both* a signification system *and* communication (understood as a set of messages); this relation cannot be understood as an either–or. Therefore, language phenomena are conceived of as a process (i.e., communication of messages) and a product (i.e., a signification system), both at the same time. Which aspect one focuses upon is determined by one's theoretical model and one's more or less explicit interests in the study of verbal messages.

As a signification system, language is viewed as an open system or semiosis. The system is not finite, but as a social reality, it is open for modifications of different kinds, such as restructuring and creativity during communication. The signification system thus

has the form of a variation grammar, a system of multifunctional potentialities, allowing for orderly variation and flexible regularities. These regularities can be described not in the form of abstract 'rules,' 'principles,' and the like, but as social norms or even potential 'resources,' i.e., arbitrary conventions grounded in communication. More specifically, grammar is conceived of as a network of relations: a systemic network, not a system of rules.

From the communication angle, language can be viewed as some socially controllable elaboration and/or modification of an earlier established reality, i.e., an already internalized system. But communication-as-language can also be conceived of as the creation of such a system. One consequence of this language conception is seen in our understanding of the language acquisition process. In this process, the child is not interpreted as a passive agent, but as an active and meaning-seeking organism trying to adapt itself during either the dialogue, interaction, or self-regulation process, towards an environment and other communicators in the environment.

Furthermore, this conception neutralizes one of the classical oppositions in the abstract, objectivist conception of language, namely that between diachronic and synchronic. As a communication process, language seeks a stability that can never be achieved. Diachronicity is an inherent quality of language; the synchronic is merely a fixation of this diachronic quality, necessitated uniquely by the conscious rationalization of a supposed mutual intelligibility, by the need for an abstract, objectivist description of language, or by the language planner's urge for codification; for all of these, translating process to product is an essential demand.

3. Linguistics and Communication

The phenomena of communication have often been thought of as peripheral in linguistic research. This view is a result of the strong hold the abstract objectivist language conception has had on modern linguistic thought. Most workers in this tradition share (implicitly or explicitly) the idea that the essence of language is to represent some intellectual structure; thus, they reduce communication to a subordinate place amongst the possible functions of language.

Some linguistic schools have advocated a more communication-relevant approach to language; here, one could name the Prague School, and different versions of linguistic functionalism. This low status attributed to communication is similarly challenged by different pragmatic approaches to language (see *Pragmatics and Sociolinguistics*), as well as by language-relevant research in related disciplines such as sociology, poetics, psychology, or anthropology. Only some of the more important and coherent attempts of such communication-relevant approaches to language will be mentioned here.

3.1 Soviet Semiotic Dialogism

In the pre-Stalin era of Soviet intellectual life, a group of scholars emerged with a more or less common view of language, cognition, and communication; the language philosopher V. N. Voloshinov (see *Voloshinov, Valentin Nikolavic*), the psychologist L. S. Vygotsky, and the literary critic M. M. Bakhtin (see *Dialogism*; *Bakhtin, Mikhail M.*; *Marxist Theories of Language*). All these scholars launched an attack on the basic ideas of abstract objectivism. For political reasons, it took a long time before their ideas reached the western world, but since the late 1960s, their approach to humanistic studies has come to play an increasingly important role in a great number of humanistic disciplines such as psychology, sociology, poetics, philosophy, semiotics, and linguistics.

The basic idea of these scholars is that language is essentially dialogic. This dialogicity is not to be mistaken for a possible external, instrumental use of language; it is dialogic in its most radical sense, i.e., that of the inner dialectic quality of the language sign. The addresser and the addressee are integrated as part of the nature of language. Language never exists as a unifunctional, closed system: rather, it is a process of communication. This process is furthermore characterized by the notions of multiaccentuality, heterogeneity, polyphony, intertextuality and in particular 'voicing' (see *Dialogism*), all referring to the social nature of language. In communication, language never appears as single-voiced: the situation, the tradition, the power relations between the communicators, and so on, all place their mark in the message. Thus, language really is this multivoiced message or speech process.

The Soviet dialogists see the nature of language as fundamentally social. The study of the content plane of linguistic messages becomes part of the study of ideology (see *Ideology*), whereas the object of study of the expression plane are the so-called speech genres. Consequently, even cognition is interpreted as a communication process, or, as it is called: 'inner speech.' Cognition or 'thought' is only possible through language; language is this multiaccentuated interaction process.

It remains to be seen whether the ideas of the Soviet dialogists can stimulate the traditional study of languages and language in the same way as they have influenced psychology and text linguistics. But one linguistic theory has emerged which partly seems to have been inspired by this school: namely the theory of enunciation and polyphony, developed above all by the French linguist Oswald Ducrot. This theory not only focuses on the self-referential aspects of language, such as deictic elements and shifters, but also on the fact that each message may have more than one source, and therefore may represent

several points of view. These qualities are grammaticalized in language, for instance in the system of modalities. One consequence of the theory is that the monolithic notion of the addresser's integrity is suspended.

3.2 The Prague School and Functionalism

The Prague School was a linguistic school which did not limit its study of language to isolated utterances in so-called 'normal' situations. Quite the contrary: its focus was on a number of different types of human communication where language was used as a tool, such as literature and film. The school's basic relevance for the study of communication lies in the Prague linguists' development of a process theory of syntax, based on the notions of *theme* and *rheme*. Theme and rheme refer to the different linguistic qualities in the message which, in the communication process, signal already given meaning as 'theme,' and introduce new meaning as 'rheme.'

An even more important contribution to a communicative approach to language study is the Prague School's development of different taxonomies of so-called communicative functions. These taxonomies play an important role in Trubetzkoy's phonological theory. Another linguist (who is often associated with the Prague school), André Martinet, also challenges the traditional view of the basic function of language as representation. To Martinet, language is an instrument for communication. Martinet's stance appears to stem (at least in part) from his view on language as serving the need for mutual understanding. This 'sociological' attitude may also be prompted by Martinet's interest in what he calls the 'vocal basis' of language and by his studies in diachronic phonology. This basic communicative function of language could, e.g., explain why certain phonemes do not merge, and why the distinctive values of a language system are retained, even though its substance is fundamentally changed.

Like the Soviet dialogists, but perhaps in a less radical fashion, the Praguians refuse to reduce the essence of language's functions to intellectual representation. To them, language is a polyfunctional potential: its different functions are grammaticalized at different strata in the language system. Moreover, each individual utterance of a language is seen as a potential which in the interpretation process is reduced and given a coherent structure. Interpretation thus happens according to a more or less conscious choice of what is called a 'dominant': among the possible functions of an utterance in a specific communicative situation, the one is picked that is felt to be the most important for the message. It was in this way that Roman Jakobson explained the poetic quality of language: not as something extrinsic, but as an inherent quality.

3.3 Rommetveit's Message Structure Theory

The Norwegian psycholinguist Ragnar Rommetveit developed his theory of message structure over the years 1968–90, often in opposition to dominant paradigms in American linguistic research, such as Generative Grammer and Montague Grammar. The theoretical basis for his theory is a combination of experimental psychology (e.g., experiments with word associations), G. H. Mead's symbolic interactionism, and the European hermeneutic tradition. In fact, Rommetveit has made a point of being a methodological pluralist.

Rommetveit's basic idea is that language is embedded in a social matrix or context (see *Context*). Language can never be studied in isolation from the interaction of context. The analysis of interaction and communication is then related to the actual needs, feelings, intentions, and understanding of the subjects involved and their life worlds. Therefore, meaning is necessarily bound to context. Rommetveit attacks all ideas about 'literal' meaning, minimal semantic universals, etc., as fantasies based on theories of language that are in reality theories of written, formal language. On the content plane, messages are considered to be so-called 'meaning potentials.' Rommetveit, without being a nihilist, advocates a theory of perspectival relativity, in keeping with the sociological perspective of his theory. The social nature of language is guaranteed by so-called 'drafts of contracts.'

Contracts are seen as a process of negotiating tacit agreement and a shared world of discourse (see *Discourse*); the process is characterized by the notion of *message structure*. In the process of structuring a message, the communicators try to build a temporarily shared social reality (see *Language as a Social Reality*). The message structure consists of cyclic patterns of nesting new (or, as it is called, 'free') information into given (or 'bound') information.

To the theoretical-oriented linguist, Rommetveit's theory appears to be somewhat limited, as it seldom focuses on what the theory means in terms of the grammar. It is basically an interaction theory which focuses on the content plane of messages, not on the structure of the sign vehicle.

3.4 Halliday's Socio-semiotic Theory of Language

As a student of the English linguist J. R. Firth (see *Firth J.R.*), M. A. K. Halliday (see *Halliday, Michael Alexander Kirkwood*) was also influenced (albeit indirectly) by the anthropologist Malinowski (see *Malinowski, Bronislaw Kaspar*). Consequently, he has referred to his theory as an 'ethnographic or descriptive grammar.' Language, or as it is called, the combination of a 'semantic,' a 'lexico-grammatical,' and a 'phonological system,' is studied as the product of a social process, a *social reality* is

schematized (or 'encoded') as a semantic system. However, among the systems that construct culture (the *semiotic* systems, as they are called), language is just one, even though it has a privileged place: most other semiotic systems are obligatorily mediated through language and its system. The product of the social process is the 'code' (see *Code, Socio-linguistic*); human behavior is essential for its explanation. In Halliday's words the 'system is determined by the process.'

Typical of Halliday, then, is the endeavor to explain the structure of language as a consequence of some dialogue, of which it is in some way an abstraction. As this dialogic process is determined by the exchange of commodities, language is both determined by the nature of the commodity (such as 'goods and services' versus 'information'), and by the rules defined for the commodity exchange (such as 'giving' and 'demanding'). However, this is not a monolithic process: language develops characteristic realizations at its different levels in accordance with what Halliday calls 'congruence patterns.'

Thus, Halliday's theory of language is structured as a system network, where the expression plane is conceived of as manifestations of meanings chosen from a semantic system (the encoded social reality). While the notion of 'choice' is central to Halliday's theory, it should not be mistaken for a conscious act of choosing, but understood as a term referring to the processual nature of the socio-semiotic system of language.

4. Future Work

A great deal of what has been discussed above is often classified as belonging to the domain of 'pragmatic' in linguistics. But if pragmatics is conceived as a superficial attribution to, or even as a 'waste-basket' for the more systematic, and there-fore more prestigious, studies of syntax and seman-tics, this is a misrepresentation (see *Pragmatics and Sociolinguistics*). Among the fundamentally radical views that some of the most important communica-tion-oriented linguists share not least the four 'schools' explicitly mentioned here have inspired, or are still systematically searching for such an alter-native. For the linguist who is skeptical about most of the traditional conceptions in linguistics associated with what has been referred to here as 'abstract objectivism,' there exists several research alternatives.

Communicative Competence

A. Duranti

The notion of 'communicative competence' was introduced by Dell Hymes in the late 1960s to express the idea that the ability to speak a language requires more than the knowledge of grammatical

rules (Hymes 1972, 1984). Children grow up in the midst of verbal interactions in which they need to pay attention not only to grammatical form (e.g., the order of words and their inflection) but also to the implications, for themselves and other participants, of what is said. To the extent to which linguistic research is concerned with the association between forms and meanings, it should recognize that any linguistic expression is associated with and often reproduces a set of attitudes, values, and beliefs about the world. To be a fluent speaker means to be able to recognize and exploit such attitudes, values, and beliefs. Furthermore, language is often only one of the codes used for communication. Speakers complement, refine, and sometimes neutralize or even contradict the meaning of words they use by relying on gestures and eye gaze, and by the use of tools and other material resources around them. The notion of communicative competence was also meant to encourage the study of different codes and modes of communicating within and across situations. Although the term 'competence' echoes Chomsky's (1965) use of the same word, the addition of the adjective 'communicative' broadens the object of inquiry. Furthermore, while Chomsky's notion of competence refers to an abstract set of (typically unconscious) rules—based on an innate language faculty and independent of actual usuage—Hymes' notion of competence refers to the knowledge necessary for adequately communicating in real-life situations. Hence the attention to what speakers actually do with language that is implicit in the notion of communicative competence is not only a methodological but also a theoretical concern. That is, it not only allows us to start from what people do with language in order to infer what they need to know, but also recognizes that knowledge of language is gained from participation in actual communicative events, implying the simultaneous reliance on a number of semiotic resources and the collaboration of other participants. In this sense, Hymes' notion of competence is not separate from the notion of performance—the use of language—as it is in Chomsky's model.

The introduction of the notion of communicative competence was consistent with Hymes' (1964) earlier call for a new interdisciplinary field, the 'ethnography of communication' (sometimes called the 'ethnography of speaking') (see *Ethnography of Speaking*). This field is dedicated to the empirical study of patterns of speaking in different communities around the world. Theoretically, it draw from a number of traditions, most notably Roman Jakobson's functionalism as represented in his 'speech event' model (Jakobson 1960), from which Hymes derived his notion of 'communicative event,' which is a unit of analysis conceived for the study of communicative competence (see *Ethnography of Speaking*). In this framework, speaker competence is no longer defined exclusively in terms of their knowledge of grammatical rules, but is also defined in terms of the range of communicative events in which they can participate. Such a range defines person's 'repertoire' within a given community.

The term communicative competence is also used in other disciplines by authors such as Habermas (1970), albeit with different theoretical implications from the ones discussed above (see also *Hymes, Dell Hathaway*).

Ecology of Language
J. M. Y. Simpson

The 'ecology' of an organism is the set of relationships between that organism and its environment. The term 'ecology of language' was introduced by the Norwegian—American linguist Einar Haugen (see *Haugen, Einar*) to describe the relationships between a variety of language and its surroundings. Such

surroundings include geographical entities, human beings, and other varieties of language. The investigation of the ecology of a language therefore deals with such topics as where the language is spoken, by whom it is spoken, and what other varieties of language are spoken in the same region; furthermore, it studies any observable interactions among the language, its speakers, and other languages.

The articles in Section 6 are those most closely concerned with the ecology of language, strictly defined, together with certain of those in Sections 5, 7, and 8. However, it has to be said that almost every article in this Encyclopedia could be regarded as revealing some aspect of the ecology of language.

Language

J. M. Y. Simpson

'Language' has two different yet related meanings, related in that both are concerned with human behavior of a particular kind. The difference in meaning correlates with a grammatical difference, namely whether the word is used as a mass noun ('language') or as a countable noun ('a language'). In this article these two meanings are examined in turn.

1. The Term 'Language'

The mass noun 'language' is in fact used in several ways. It may be used of human behavior on a particular occasion when an individual speaks or writes or signs: he or she may be said to be 'communicating in language.' This ability is often held to be the distinguishing mark of the human race and it makes possible the existence of human society. Such behavior is of course not random but takes place in accordance with a system or, more precisely, with an intricate complex of systems. This particular use of 'language' is central to this Encyclopedia in that every article deals with some aspect of such human behavior and its role in society.

'Language' may also be used to refer to the biological faculty of the human mind which makes the above behavior possible—this is the sense in which it is frequently used in psycholinguistics, one area of which studies the 'language acquisition device' of the human mind which enables an infant to learn how to communicate in language. This is also the sense in which it is used by neurolinguists when they identify 'language areas' of the human brain.

'Language' may also be used to refer to all systems of speaking and writing, as in the sentence 'Human language can talk about an infinite number of topics.' A great amount of effort has gone into the investigation of the properties that characterize all these systems, in other words into the defining properties of human language.

A particular type of speaking or writing felt to be typical of, or appropriate to, a given type of situation may also popularly be called 'language,' as in the phrase 'scientific language.'

In popular usage 'language' is also extended to systems of human communication other than speaking, writing, and signing, as in phrases such as 'body language' and 'the language of gesture.' Computer scientists, logicians, and mathematicians for strictly limited purposes construct notational systems which they call 'languages.' And it is common in some quarters to refer to 'animal language.' None of these systems would be described by linguists as 'language,' on the grounds that they do not possess the defining properties of human language.

2. The Term 'A Language'

The countable noun 'a language' is used to refer to an abstract system underlying the behavior in speech, writing, or signing of an entire community; to put it more simply, 'a language' is regarded as a system of speaking, writing, or signing common to a group of people. Thus French is thought of as 'a language spoken by Frenchmen' or American Sign Language as 'a language used in the USA.' This interpretation of 'a language' is probably the most common in contexts outside linguistics. Unfortunately, it is by no means easy to define what 'a language' might be.

2.1 The Twofold Fallacy of 'A Language'

A common assumption is that languages are separate entities. It is assumed, for example, that Arabic, Dutch, English, French, German, Italian, and Scottish Gaelic are seven 'languages' and this assumption is supported by the facts that teaching-grammars are on sale for all seven and that various educational and political institutions recognize them as 'languages.' Moreover, certain atlases

include maps with captions such as 'Languages of the World,' in which the geographical distribution of such 'languages' is indicated by areas of different colors; one block of color does not merge into an adjacent block of a different color: the change between them is quite abrupt (see, for example, *The Times Atlas of the World: Comprehensive Edition*, London 1967, 5th edn. 1975, rev. 1977: Plate 6 'World Mankind, Languages'). Thus it is easy for the layman to assume that languages are distinct from one another (because of such maps) and that each represents a homogeneous system (because of teaching-grammars which reveal this system). However, both parts of this assumption are false.

2.2 Languages Can Merge into One Another

In the first place, some languages do merge into others, unlike the areas of different colors in maps. Dutch and German are held to be two different languages, as has been indicated, and admittedly the comparison of a newspaper written in Standard Dutch with one written in Standard German would seem to bear this out. Yet standard languages are abnormal varieties of language, in the sense that they come into being by deliberate intervention on the part of society; 'on the ground' there is no sharp break between so-called 'Dutch' dialects and so-called 'German' ones.

To take one very simple example: the Standard Dutch form meaning 'I do' is *ik maak* (also found in certain Dutch dialects) and the Standard German is *ich mache* (also found in certain German dialects); but in the dialect of Düsseldorf the form is *ich make*, representing a kind of halfway house between the two other forms. Copious other examples of similar phenomena can be found, affecting not only consonants and vowels but also grammatical features and vocabulary. Indeed it is possible to travel down the River Rhine from an area where a Swiss German dialect is spoken to a Dutch-speaking area on the North Sea without encountering any sharp linguistic break; at the extremes. Swiss German and Dutch are mutually incomprehensible, but it is safe to say that on the Rhine the inhabitants of any one town can understand without difficulty those of the next town upstream and those of the next town downstream. Such an area can be referred to as a 'dialect continuum.' Instead of the two linguistic areas 'German' and 'Dutch' which a simplistic map of languages shows, there is one linguistic area composed of related varieties and in this one area not everyone can understand everyone else.

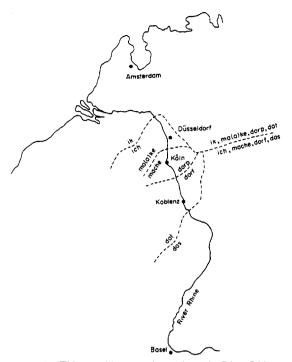
A very selective set of linguistic features illustrating these gradual linguistic changes met with on a journey down the Rhine are shown in Fig. 1; this illustrates only differences in sounds and it ignores differences in grammar and vocabulary.


Figure 1. This map illustrates how, along the River Rhine, there is a gradual transition in German–Dutch dialects from an area in the north in which the words for 'I,' 'do,' 'village,' and 'that' are pronounced *ik, ma(a)ke, dorp,* and *dat* to an area in the south in which they are pronounced *ich, mache, dorf,* and *das.*

Such merging of one language into another is not peculiar to German and Dutch. French dialects merge into Italian ones, so that there is another large linguistic area that stretches from Normandy to Sicily; indeed since French dialects also merge into Spanish ones, and Spanish ones into Portuguese ones, this linguistic area must be expanded to include the Iberian peninsula. A similar situation is seen in the gradual transition between dialects of Czech and of Slovak, and of Czech and of Polish; the latter in turn merge into dialects of Belorussian, Ukrainian, and ultimately Russian. A fourth linguistic area of this kind in Europe is that in which dialects of the mainland Scandinavian languages—Danish, Norwegian, and Swedish—are spoken. Dialect continua are by no means a phenomenon peculiar to Europe, another celebrated example is afforded by the Indo-European varieties in Northern India.

To return to the particular case of 'German' and 'Dutch' dialects, there is no reason for considering any one difference between them as being more important that any other and there is therefore no linguistic reason for postulating a boundary where

32

'German' ends and 'Dutch' begins. Any such division is made on political grounds, between 'dialects spoken in The Netherlands and Belgium' and 'dialects spoken in the Federal Republic of Germany, Austria, Liechtenstein, and Switzerland.'

Allusion was made above to the popular view of *a language* as 'as a system of speaking or writing common to a group of people'; but in the case of each dialect continuum mentioned above no single ystem *is* discernible. It will be apparent that one has no independent, universally applicable linguistic criterion by which one 'language' can be singled out as opposed to another, genetically related, one. Linguistics cannot tell what 'a language' is and so the meaning of what would appear to be one of the basic terms has, so to speak, disappeared. There is no precise definition of *a language* available.

2.3 'A Language' Is Not a Homogeneous System

The second aspect of the above-mentioned fallacy concerning languages was that each represents a homogeneous system. But in fact something that is widely recognized as 'a language' need not be a homogeneous system: Standard English, for example, exhibits all sorts of variations in pronunciation, in grammar, and in vocabulary.

For instance, most Scotsmen will pronounce the word *pay* with a monophthong, a vowel of unchanging quality, whereas Londoners (and indeed the majority of Englishmen) will pronounce it with a diphthong, a vowel of continuously changing quality; to Scottish hearers the Londoner will sound as though he or she were trying to say *pie*. Not only the pronunciation of individual sounds may vary, the number of sounds at the disposal of speakers may be different. American and English speakers make a distinction between *pool* and *pull*, Scottish speakers do not. Conversely, most English speakers do not distinguish between *wail* and *whale*, Scottish speakers do. There are hundreds of such differences in the English-speaking world (Wells 1982) as well as additional differences in intonation patterns and in voice quality.

Differences of grammar within Standard English are fewer, but they exist: for example, Scottish and North American speakers can utter a sentence such as *The cat wants out*; the English version is *The cat wants to go out*. A Scotsman may remark *The woodwork needs painted*, a sentiment that an Englishman renders as *The woodwork needs painting*. In fact, Trudgill and Hannah (1982) devote some 25 pages (out of a total book-length of 130 pages) to grammatical differences between English English and North American English.

Vocabulary differences are much more numerous than differences of grammar. The same word may have a different meaning in two varieties: *homely* (of a person) in British English means 'warm and domesticated in manner or appearance' but in United States English it means 'ugly.' Alternatively, the same item may have different names in different varieties: a British car-owner will have a *silencer* on his vehicle but an American will have a *muffler* on his; an Australian child may ruin his teeth by eating *lollies*, a British one by eating *sweets*. Such differences amount to several hundreds and can lead to confusion.

The last three paragraphs have dealt with regional differences. But differences within English and other 'languages' may correlate with non-regional factors, such as social class, caste, tribe, sex, religion, occupation, or even political allegiance. Moreover, differences in the types of situation in which 'the language' is used (for example, an informal conversation, a formal lecture, a religious ceremony, a news report, a poem), or the role of a speaker or writer in such situations, may impose the selection of particular styles of speaking or writing.

Most importantly, individuals may not always exhibit complete uniformity in speaking (or indeed in writing). They may vary their linguistic behavior according to their partner in conversation (see *Speech Accommodation*) or for reasons that are not immediately discernible.

Variation of the above types seems to be a vital factor in perhaps all instances of human linguistic behavior and the identification of it, the reasons for it, and the implications of it, are a crucial area of sociolinguistic investigation (see the articles in Sections 4 and 5). The study of such variation within 'a language,' though by and large ignored by general linguistics until the 1960s, is now seen to be a vital component in our understanding of how 'language' works.

2.4 'A Language': A Useful Term Nevertheless

The conclusion is that 'a language' is not definable in linguistic theory. No firm boundary can necessarily be drawn between one language and another and one language may contain vast differences of pronunciation, grammar, and vocabulary. The question now arises why the term 'a language' is so widely used and why it is undeniably so useful. There are various answers to this question.

In the first place it may be that a given group of speakers feel that in spite of regional or other differences they all speak 'the same language.' This can be observed in writings by Germans from the earliest period: Otfrid in the ninth century tells us that he is writing 'in German' (his Latin term is *theotisce*, his German phrase *in frenkisga zungun*). In the subsequent history of German, it is never questioned that there is one 'German language,' in spite of extreme dialectal differences. This 'German' includes Plattdeutsch spoken in the north of the

country, and 'German' is felt to be something different from Dutch. From the point of view of a descriptive linguist, however, Plattdeutsch resembles Standard Dutch more closely than it does Standard German. In this particular instance, political considerations have underpinned the popular view in modern times. By the same token, tribal affiliations may influence popular judgments on what are different languages.

A second answer is that a given standard language (see *Standardization*) is held to be *the* language and related varieties, which may or may not be intelligible to the speaker of the standard, are held to be dialects of the standard. But again there may be differences of opinion on how close this relationship must be before a variety can be regarded as a dialect of one language or how distant the relationship must be before a variety is regarded as a different language. Sardinian for example, is variously held to be either a dialect of Italian or a language distinct from Italian. On the other hand, Danish, Norwegian, and Swedish are so similar that they could quite easily be held to be three dialects of the same language; however, since Danish and Swedish are standard languages (while Norwegian has two standards), there is never any question of regarding them as anything other than 'languages' in their own right.

A third possible answer is that 'a language' is a convenient label attached by a scholar to name a variety of language in which he or she is interested. He or she may indeed leave the question open whether or not this variety is subsequently to continue to be regarded as one language or a group of related languages.

Teaching grammars that will allegedly teach one to speak and write a 'language' such as 'Arabic,' 'Albanian,' 'French,' and so on in fact purvey abnormally restricted varieties of language with few (if indeed any at all) of the variations noted above. These books do not reflect reality. Nevertheless, they are useful, indeed indispensable, for beginners would find the complexities of native language-behavior quite bewildering. In this connection it is relevant to point out that one does not expect an obvious language-learner to have a native mastery of all the variations in a variety of language and one may, in fact, talk to a learner in a nonnative manner (see *Foreigner Talk*).

It will be obvious that the impossibility of defining 'a language' as a technical term in linguistic theory does not prevent the widespread use of the phrase, especially in popular speaking or writing. But within linguistics, and especially in sociolinguistic investigation, the term tends to be avoided and the neutral description 'variety' or 'variety of language' is used instead.

Language as a Social Reality

T. Pateman

A social reality is any causally efficacious system, structure, or mechanism which can exist independently of any particular historical individual, but cannot exist independently of some group of individuals somehow linked together in sustaining or reproducing that reality from day to day (Bhaskar 1979, Durkheim 1982, Giddens 1979). So French is an existing social reality which preexists any infant born into a French-speaking society and which is causally efficacious in bringing it about, all other things being equal, that the infant ends up speaking French. In contrast, Cornish—like every other dead language—is not a social reality. It is not now sustained as a living language by any group of individuals, nor is it causally efficacious in producing any new speakers of Cornish by the usual mechanisms of language development, whatever those are. Cornish is merely an object of linguistic study.

Individuals may sustain (reproduce) a language from day to day without knowing that is what they

are doing, or needing to have as a goal or intention that they do it. Someone may use British Sign Language without having the belief or knowledge that they are using it—they may believe no more than that they are signing. Someone may speak English, knowing that they do so, but careless of whether their actions reproduce English in any particular form. Linguistic prescriptivism requires the reflexive monitoring (Giddens 1979) of speech and writing by individuals with the objective of ensuring that a language (their own or, for example, their pupils') is reproduced in some particular, valued form. Because of the tendency to change inherent in all language use, prescriptivism is essential to language maintenance (Pateman 1987). This is very obvious in the case of written forms, but is equally true for spoken ones.

Any discussion of language as a social reality will soon encounter the problem of the identity conditions for a language, which troubled Saussure (1983) and others since. How can the same thing (say, English) be different over time? In all probability I learnt to speak from people who learnt to speak from people who…spoke Anglo–Saxon. Some consequences of language change are catastrophic (in the sense of catastrophe theory): despite the unbroken chain, I do not understand Anglo–Saxon. There is a breakdown of mutual intelligibility. On the other hand, Danish, Norwegian, and Swedish are counted as separate languages despite a high degree of mutual inter-intelligibility (Haugen 1972). Pateman (1987) has put forward the view that languages are best regarded as social facts (realities) which are not linguistic facts, developing Chomsky's distinction between E(xternal) and I(nternal) languages (Chomsky 1986), which is a distinction between languages as a social reality and language as a psychological reality. (For further discussion see Chomsky 2000.)

As already implied, coordination of speakers' actions on a common target language is by no means necessary to successful communication. There are both centrifugal and centripetal forces at work in language learning and language use. Centripetal forces do lead to mutual adjustment towards a regularity which can then become normative as a standard of right and wrong. The emergence of norms in this way is explored in Ullman-Margalit 1977, drawing on the pioneering work by Lewis (1969 though for a critical discussion of Lewis, see Gilbert 1989). Such mechanisms are distinct from, and prior to, conscious planning and prescription.

If French is a social reality and Cornish is not, at least in the required sense, this implies that a language can be described without invoking a social reality for it. This is a necessary condition of the possibility of autonomous linguistics, though not a sufficient condition, since some other kind of reality (e.g., psychological) might still have to be invoked

(Katz 1981, 1985.) However, it is arguable that dead and living languages are different in that whilst a dead language can in principle be fully described by a grammar, this is not even in principle possible for a living language. It has been argued that living languages are open-ended and, specifically, never fully conventionalized social realities or fully determinate psychological realities. There is always scope for individuals using 'a language' to create new forms which were not already implicit in social conventions or internal psychological rules. On this view (for which see Croce 1967, Harris 1981, Matthews 1979, Sampson 1979, 1980), there can be true intuitions of grammaticality which do not derive from preexisting rules just as there can, on a view deriving from Kant, be true judgements of beauty which do not derive from rules of beauty (Mothersill 1984, Pateman 1997). Such intuitions are not in the requisite sense obviously social: they may be distributively shared by individuals, but they are not socially derived. This view is anathema to 'strong' social reductionists, such as Bourdieu 1991 and, perhaps, Itkonen 1978. Equally, it raises doubts about the possibility of an autonomous linguistics, this time from the side of individual psychology.

Language is, however, clearly a social reality when its resources—its symbolic powers—are used by speakers in efforts to affect other social realities. So, for example, in hypercorrection language is being used to affect perceived social status relationships and all that then follows from the estimation of those realities. Such phenomena have been studied by both linguists and sociologists, operating within different scientific traditions, exemplified by Labov (1966) and Bourdieu (1991).

Language in Society: Overview

M. L. Apte

It is axiomatic that language is an essential and significant part of the concept of culture and that it enables human beings to form stable social–structural aggregates. While the nature of language has been studied in depth for more than two thousand years going back to the Greeks and Indians and manifesting the results in such remarkable achievements as Pānini's Sanskrit grammar, the development of linguistics in the twentieth century has been primarily achieved due to the separation of language from its sociocultural moorings. Yet this very embedding of language in society and culture has been the focus of intense and sustained research efforts since the 1960s.

The aim of this essay is to provide an overview of these theoretical and methodological developments and the resulting insights that have been achieved concerning the multitudinous nature of the relationship of language to society and culture. In this endeavor, the fundamental concepts relevant to the development of sociolinguistic theories will be discussed and the important areas of significant research highlighted.

A crucial aspect of the human sociocultural evolution has been the development of language. While communication occurs among various animal and insect species, human communication is probably the most complex. Human language is evolved to such a degree that for many social scientists it is the sole criterion separating humans from the rest of the animal world (Chomsky 1965). Scholars (Hockett 1960) have systematically tried to delineate those properties of the human communication system that separate it from others.

1. Anthropological and Linguistic Origins

As anthropologists are interested in investigating all aspects of human existence, language is a major topic in their research. It is well-recognized that culture is transmitted over time through language. Linguistics and the study of language were inseparable from anthropological and folklore studies in America before the twentieth century; note, for example, that the founders of the American Folklore Society, American Ethnological Society, and American Anthropological Association were determined to classify Native Americans on the basis of their languages.

In Europe, language was studied as part of logic, rhetoric, and philosophy throughout the ancient and medieval periods. From the beginning of the eighteenth century, linguistic studies became comparative and historical in nature, focusing on the origin and evolution of language. Contemporary European languages were traced to their common ancestor(s) through comparative methods. The discovery that Sanskrit, the classical language of India, was structurally and lexically similar to Greek and Latin, the classical languages of Europe, accelerated this emphasis on historical and comparative linguistics. The study of the Indo–European language family became the most important task and the Indo–European model was used for writing the grammars of non-Indo–European languages.

This situation began to change at the start of the twentieth century. The linguist Ferdinand de Saussure developed revolutionary ideas about the nature of language, and Boas, Sapir, and Bloomfield laid the foundation of modern linguistic science in the USA. The scope of linguistic inquiry was narrowed so that language was studied in and of itself. Language was increasingly seen as a system with a structure.

The objective of linguistics became not only the writing of structural descriptions of as many languages as possible, but also the developing of a

36

universal conceptual and theoretical framework which could be the foundation of language-specific grammars. This orientation led to the development of a universal system for transcribing speech sounds—the International Phonetic Alphabet—and the creation of such universal linguistic concepts as phoneme and morpheme. Structural descriptions of individual languages were presented in terms of phonological, morphological, and syntactic units and their relationships. Sentence was considered the largest, and speech sound the smallest, unit of analysis. Formalism was emphasized because of the so-called scientific perspective of empiricism, and rigorous methodology was developed for systematically eliciting linguistic data while doing fieldwork. Discovery procedures became the basis of fieldwork. The emphasis changed to describing language as spoken rather than as written. Prescriptive attitudes were replaced by descriptive orientation.

The first half of the twentieth century witnessed an extraordinary growth of linguistic theory, the gathering of linguistic data, and structural analyses of diverse and so-called 'exotic,' unwritten languages. Phonological analyses of these unwritten languages were used in adopting the Roman script for writing them.

Although the emergence of generative-transformational theory shifted the emphasis from fieldwork and the earlier conceptual framework based on structuralism, linguistics did not move away from the study of language in isolation. It became even further abstracted, focusing on the linguistic competence of the ideal speaker–listener (Chomsky 1965: 3–4) formalized by way of rule-oriented grammars of languages without considering the linguistic performance of the average language speaker in a sociocultural context.

While both the structuralist and the generative–transformational theories with their focus on language in isolation dominated the field of linguistics in the twentieth century, there had existed a small coterie of influential linguists such as Boas, Sapir, and Whorf who investigated not only the psychological and cognitive aspects of language but also its multitudinous linkages with the rest of the human sociocultural system (Carroll 1956; see *Sapir–Whorf Hypothesis*).

It was not until the 1960s, however, that attention began to be focused on language variation, use, and function, to understand the nature of the relationship between society and culture on the one hand and language on the other. Increasingly language, was being studied as a social and cultural institution. In part, this focus was also a reaction to the isolationist tendencies of generative–transformational linguists. Their emphasis on the abstract nature of language and their focus on the linguistic competence of the ideal speaker–listener meant that there was no room

for the individuals' socioculturally influenced linguistic performances in everyday life. Thus began the development of the fields of inquiry that came to be known as sociolinguistics.

Sociolinguistics as a field of inquiry includes all aspects of the relationship between language on the one hand and society and culture on the other. Even psychologically and politically oriented investigations of language have occasionally been subsumed within this field. Such nomenclature as ethnolinguistics, psycholinguistics, language and politics, linguistic anthropology, sociology of language, as and when used, primarily suggest either disciplinary or topical focus within the broad field. Several edited and single author textbooks with titles such as *Sociolinguistics, Introduction to Sociolinguistics* (Gumperz and Hymes 1972, Pride and Holmes 1972, Trudgill 1974a, Mesthrie et al. 2000) present the field with the broadest possible scope.

2. Culture, Meaning, and Context

A study of the relationship of language to culture and society necessitates an understanding of the fundamental concepts of culture, meaning, and context. The most prominent emphasis in sociolinguistic research in recent years has been on developing theories to explain the nature and function of these concepts and their importance in understanding language.

2.1 Culture

There exists a large body of literature in anthropology delineating the concept and various theories of culture (Kroeber and Kluckholm 1952, Keesing 1974, Schneider 1976, Shweder and LeVine 1984). A major theoretical orientation is to consider culture as a system of symbols and meaning (Schneider 1976; Sherzer 1987). Human beings create symbols by which an element, be it an object, action, event, person, etc., is arbitrarily associated with a specific meaning. For Schneider (1976) 'culture places disparate parts of the social system together into a meaningful whole.' Culture is also viewed as a system having a separate and independent existence from that of the individuals who manifest it in their behavior. This view is in some ways comparable to the language/speech (*langue/parole*) dichotomy of Ferdinand de Saussure, who maintained that language (*langue*) was a social institution with an independent existence over and above its acquisition by individuals who manifested it in their speech (*parole*).

Despite a century of efforts to define culture adequately, there is no agreement among anthropologists regarding its nature. This is not surprising, as most basic concepts in a discipline are refined repeatedly as new knowledge, ideas, and paradigms replace old ones (Kuhn 1970). The change in cultural anthropology since the 1960s has primarily been one

of a new perspective. Rather than viewing culture as uniform, largely static, holistic, and deterministic, the new orientation is to view culture as complex, varied, and dynamic in nature.

Culture has also been perceived in terms of a model *of* and *for* reality, the underlying assumptions of which motivate human action (Geertz 1973). Individuals internalize this model without necessarily being aware of doing so. There is also an emphasis on formalizing the nature of culture by trying to develop models presumably internalized by individuals and groups. Just as in linguistics considerable research has been devoted to understanding the nature of language acquisition, so research efforts in cultural anthropology have been directed towards understanding how individuals acquire culture and, once acquired, how they retain it, use it, and add to it.

If culture is viewed as a symbolic and meaningful system, certain fundamental questions arise: How can its symbols and meanings be extrapolated? How can they be adequately analyzed and described? By what techniques can meanings and symbols be identified, and what methods can be used towards this objective? What are the ways, if any, of independently verifying constructs of cultural systems that are associated with particular human aggregates as being true? These are important questions for cognitive scientists and anthropologists interested in discovering the role of cognition in cultural investigation, and in endeavoring to answer them they have increasingly focused on language, which combines form and meaning in numerous ways and shapes the natural world for its speakers. The aim, then, is to construct theories of both culture and meaning.

2.2 Meaning

In the development of structural linguistic theory and in its application for writing grammars of individual languages, meaning, however the concept was understood, did not have a central position. Bloomfield's most influential work does include a chapter on meaning (Bloomfield 1933: 139–57), but his theoretical approach is based on the notion that 'The statement of meanings is...the weak point of language-study, and will remain so until human knowledge advances very far beyond its present state.' A similar note of caution pervades later structuralist works. Gleason (1961: 172), for instance, speaks of the 'difficulties...in making clear statements about language on the basis of meaning.' A result of these tendencies was that the study of meaning in language was for a time primarily the concern of linguistic philosophers. This situation changed, however, with the advent of generative–transformational theory; for linguists of this school, an essential part of a grammar of a language was a separate, though integrated, semantic component.

For many researchers, the study of meaning and the study of culture are inseparable. Therefore, there is an increasing focus on including the concept of meaning as part of the cultural and linguistic systems (Basso and Selby 1976). The objective is to understand how cultural encyclopedic knowledge is acquired and expressed by individuals, enabling them to participate in social interactions and to communicate their thoughts, ideas, intentions, motivations, and emotions, and the underlying cultural values and ideologies. There is no single or uniform approach to the study of meaning. Although, traditionally, meaning was considered to be the domain of semantics (Leech 1981), more recently meaning has been the object of multidisciplinary and interdisciplinary research. Philosophy, psychology, linguistics, literary criticism, and anthropology all claim to be interested in studying meaning, though for different purposes and with different orientations.

Extensive research efforts have been aimed at finding answers to such questions as the following: What are the underlying principles of human cognition? Is cultural knowledge systematized and, if so, how is it organized? Do different models of cultural knowledge exist for different kinds of activity, such as talking or doing things? If so, how are they related? Are these models reflected in or represented by language and can they, therefore, be articulated? How do humans formulate their experiences into concepts and what is the nature of the human conceptualization process in its broadest sense? Do the processes of language acquisition and cultural acquisition go hand in hand? How do the conceptual categories labeled by cultural symbols get organized as part of the mental model? How are these categories reflected or represented in language? Are there cultural models of reality as reflected in language and thought?

There is a long tradition in linguistics going back to Boas, Sapir, and Whorf, who concerned themselves with understanding the linkages between language and cognition. This concern received an additional input from psychologists in the 1950s (Brown and Lenneberg 1954, Hoijer 1954).

Human beings' ability to comprehend the meaning of any linguistic communication depends in large part on how their cognitive maps are set up and how they understand the natural and social world around them. The reverse is also true, that is, human beings' ability to understand the natural and social world around them develops through their acquisition of language. Both these processes lead to internalizing encyclopedic cultural knowledge including types of meanings. Meaning is itself a multifaceted and multipurpose concept. Research in semantics has concentrated on lexical and syntactic meaning, while anthropological and sociolinguistic research has focused on the ways in which the meaning of

linguistic discourse is influenced and/or shaped by sociocultural factors.

For an average speaker of a language, the most relevant meaning is the referential one whereby s/he grasps the connection between the sound sequence uttered and the human, animal, or inanimate object in the empirical world. However, in semantic studies various types of meanings are recognized, such as conceptual, connotative, social and affective, reflected and collocative, associative, and thematic; Leech (1981: 9–23) refers to these collectively by the phrase 'communicative value.' Interestingly, all these meanings exists in an individual's communicative repertoire and are used in social interaction, though s/he may not always be conscious of them unless her/his attention is drawn to them; metamessages, that is, messages about linguistic messages, are heavily laden with them (Tannen 1990)

Meaning is also presented in terms of: (a) oppositional pairs, such as synonymy and homonymy, denotation and connotation, core and peripheral meaning, lexical and grammatical meaning, abstract and concrete meaning, analytic and synthetic meaning, and referential and metaphorical meaning; and (b) presuppositions underlying any conversational interaction.

2.2.1 Theories of Prototype and Metaphor

In the quest for an understanding of the relationship between meaning and culture, theories of prototype and metaphor have gained considerable saliency. The basis of all cultural and meaning systems is considered to be concept formation. According to prototype theory (Rosch 1976), concepts can best be viewed as prototypes. A 'bird' for example, is not best defined by reference to a set of features that refer to such aspects as wings, egg-laying capacity, two legs, warm-bloodedness, ability to fly, etc., but, rather, by reference to typical instances, so that a prototypical bird is something more like a sparrow or a crow than it is like a turkey, penguin, or ostrich. The whole idea behind this proposition is to find out how people classify objects of various kinds according to what they regard as being typical instances rather than categorizing them by a set of defining features.

A major advantage of prototype theory is the degree of flexibility it allows in understanding how people acquire concepts and use them in their language. Prototype theory predicts that in people's use of language some concepts are necessarily 'fuzzy,' which allows speakers to be creative or to be deliberately ambiguous in their linguistic usage.

Prototype theory can be applied to social situations in which speech occurs. When participants hear a new linguistic item, they generally associate it with the typical context in which it occurs or with the person who uses it. Only a few instances are needed to enable participants to carry out such a task. This is generally the manner in which individuals acquire their competence in the social use of language.

Another major effort to understand the relationship between meaning and culture in the late twentieth century has been through the study of metaphor. While tropes in general have been intensively studied in philosophy and literature, the emphasis, during the second half of the twentieth century has been on understanding how metaphors contribute to the cognitive process and how they constitute the foundation of a culture-specific worldview. The study of Lakoff and Johnson (1980) is a significant contribution in this direction.

Lakoff and Johnson claim that metaphors can never be comprehended independently of their experiential basis; nor can they ever be adequately represented without such a basis. On the basis of extensive linguistic evidence from American English, they demonstrate the following significant aspects of metaphors: (a) metaphors are based on human spatial orientation such as up–down, in–out, and front–back, yet such spatial orientation can lead to the formation of different metaphors across cultures; (b) metaphors are 'ways of viewing events, activities, emotions, ideas, etc., as entities and substances' (p. 25); (c) some metaphors are more basic and dominant than others, and the metaphors which are dominant vary from culture to culture; and (d) metaphors are pervasive in everyday language and thought. The theories of prototype and metaphor described above are illustrative of the current multidisciplinary efforts at developing universal theories of meaning within the context of language and culture (Austin 1962, Basso and Selby 1976, Black 1962, Searle 1969).

2.2.2 Worldview and Linguistic Relativity

In his introduction to the *Handbook of American Indian Languages*, Boas (1911) alluded to the unconscious nature of language proficiency in relation to the rest of the sociocultural system. In their writings, both Sapir (Sapir 1921) and Whorf (Carroll 1956) explored the nature of the relationship between linguistic structure and cultural worldview. They expressed the view that the greater the structural and lexical differences between languages, the more the diversity in the worldview of their speakers. This view became known variously as the linguistic relativity principle and the Sapir–Whorf hypothesis (see *Sapir–Whorf Hypothesis*). This hypothesis is most explicitly stated in Whorf's essay *Science and Linguistics*. Whorf tried to demonstrate the validity of this hypothesis by writing several articles on Hopi, a Native American language, emphasizing how the concept of time was perceived differentially by speakers of Indo–European languages and those of the Hopi language. He also focused on covert

grammatical categories which he claimed influenced much of the thinking of language speakers.

Linguistic influence on cognition is, however, at the unconscious level, without the speakers being aware of it. During the enculturation and socialization processes, individuals internalize the ready-made categories available to them by way of lexical items and grammatical structure and learn to relate them to external reality.

Since the early 1950s the Sapir–Whorf hypothesis has been discussed extensively (Hoijer 1954, Schaff 1973) and continues to be tested through experimental studies and through varied interpretations and applications (Kay and Kempton 1984, Lucy and Shweder 1979). Sherzer, for example, has demonstrated by analyzing examples from different cultures that an equally beneficial way to explore language-culture relationships is through discourse which 'creates, recreates, modifies, and fine tunes both culture and language and their intersection' (1987: 296).

A major development related to the Sapir–Whorf hypothesis that occurred in the 1960s was the emergence of the anthropological theory variously known as ethnoscience, ethnosemantics, componential analysis, folk taxonomy, or new ethnography. The fundamental premises of this theory were: (a) semantic domains in a language are systematically structured and this structure is reflected in hierarchical and/or paradigmatic arrangements of lexical items within the semantic domains; (b) such an arrangement of lexical items in semantic domains reflects the speakers' cognitive categorization of the universe; (c) it is possible to discover this arrangement by asking questions of native speakers in systematic and rigorous ways and to present it in a formal way; and (d) such a formal presentation reflects what goes on in the speakers' heads and represents their psychological reality.

Numerous formal analyses of lexical terms in various semantic domains of several languages were carried out. These included kinship, color, disease, animals, pronouns, plants, etc. Among them the domain of color received the most attention. Early studies (Conklin 1955, Ray 1952) demonstrated that the systems of color terminology differed widely and unpredictably in the way the 'color spectrum' was perceived in different languages, thereby supporting the linguistic relativity principle. A study based on laboratory research of more than 40 languages by Berlin and Kay (1969) demonstrated, however, the universality and linear evolution of basic color terms. Berlin and Kay demonstrated that there was a limited universal set of 11 color categories, that identification of color foci was universal, and that there was a historical sequence in which languages acquired additional color terms in increasing their basic color terminology.

Since the Berlin and Kay study, there have been claims and counterclaims regarding the language-specificity versus universality of color cognition and the nature and degree of correlation between color differentiation and terminological color categorization in individual languages (Burgess et al. 1983, Kay and Kempton 1984, Lucy and Shweder 1979).

There appears to be a general agreement among scholars regarding the following points: (a) 'languages differ semantically but not without constraint' and 'linguistic differences may induce non-linguistic cognitive differences but not so absolutely that universal cognitive processes cannot be recovered under appropriate contextual conditions' (Kay and Kempton 1984); and (b) Sapir and Whorf probably overstated their case in emphasizing absolute linguistic determinism and linguistic relativity.

2.3 Context

In sociolinguistic studies context is a key concept for understanding the nature of communication in general. While several levels of context are recognized, the primary distinction appears to be between linguistic versus sociocultural context.

Concerning the linguistic context, the analytical focus is no longer restricted to the unit of the sentence, but has been extended to linguistic texts, including naturally occurring dialogues in everyday social interaction. To participants engaged in social interaction in which language plays a significant part, it is important to know the linguistic context in terms of sequentiality, which permits them to determine the overall coherence of communication. Linguistic context also includes the phonological and grammatical features that is, phonological and prosodic cues, affixes indicating grammatical categories and morpheme classes, word order and concordal affixes, etc., that are essential for producing grammatical and meaningful sentences.

The sociocultural context can be as broad as a speech community or as narrow as an interpersonal interaction. It is varied and includes: social aggregates such as community, group, network, socio-economic class, voluntary association, and neighborhood; cultural factors such as shared knowledge, beliefs, and values; demographic and social factors such as age, sex, education, socioeconomic class, and residence; and regional, ethnic, or national identity. Awareness and/or knowledge of these aspects allows participants to connect the linguistic utterances to empirical and social reality and aids them in comprehending and interpreting the linguistic texts. Therefore, participants always look for such contextual cues, which vary cross-culturally since each culture develops its own contextualization conventions (Gumperz 1982). Depending on the size and cultural complexity of a community, such conventions may also vary intraculturally and in

some instances even interpersonally. A primary objective of the studies of language in a sociocultural context is to make the implicit sociocultural knowledge and values explicit, and to discover how various aspects of the nonlinguistic context influence the nature of linguistic communication. Native speakers of a language already possess this knowledge, albeit unconsciously, and it enables them to participate successfully in social and linguistic interaction.

Hymes (1974) discusses three main orientations for those investigating language in its sociocultural context: (a) the social as well as the linguistic; (b) socially realistic linguistics; and (c) socially constituted linguistics. The objective of those with the first orientation is to investigate language in itself, but also as it pertains to education, minority groups, politics of language and so on, in other words, practical uses of language. Scholars of the second orientation are concerned with traditional linguistic problems, such as the nature of linguistic rules and the nature of sound change, and with developing new methodologies which can result in new findings. Scholars of the third orientation are 'concerned with social as well as referential meaning, and with language as part of communicative conduct and social action' (Hymes 1974: 196–7). Hymes contrasts two fundamental approaches based on these orientations, namely, striving toward a theory of grammar as opposed to a theory of language. The structuralist and generative–transformational theoretical schools in linguistics have been concerned primarily with the former, while sociolinguistics has been oriented towards the latter.

An important issue is the extent to which sociolinguistic contexts can be formalized. Lavandera (1988: 5) mentions three important and contrasting positions regarding the problem of formalization: those of, Labov (1972), Hymes (1974), and van Dijk (1977). Labov shares the assumptions regarding formalization inherent in mainstream generative grammar and believes that his own theory regarding variable rules contributes to it. Hymes makes explicit the nature of rules that would be necessary to formalize the communicative competence of speaker–hearer. Van Dijk extends rule formulation to cover many aspects of linguistic and nonlinguistic discourse.

3. Language in Society and Culture

Perhaps the most significant consequence of sociolinguistic studies has been the awareness that language, like other sociocultural elements of human existence, needs to be viewed as having not only structural regularities but also regularities of usage; it has to be a vehicle for conveying not only information in communication but also self-expression in terms of motives, emotions, desires, knowledge, attitudes, and values.

Sociolinguistic research undertaken with the objective of pursuing the sociocultural nature of language has branched out in numerous directions. While it is difficult to demarcate clearly these divergent pursuits because of much overlapping, the sections in the remainder of this essay briefly outline the issues and discuss the relevant concepts and theories that have been proposed for the following recognized subareas of inquiry: (a) cultural patterns of language usage; (b) discourse analysis; (c) conversational analysis; and (d) correlational studies focusing on the relationship between language and social class, language and gender, and language and race.

3.1 Cultural Patterns of Language Use

One of the most important developments in sociolinguistics has been the focus on analyzing communicative competence which implies not only knowledge of language structure, but also cultural knowledge of language usage. The way to understand the nature of individuals' communicative competence in specific cultures is to analyze their linguistic performances in varied social situations and interactions. As sociolinguists and anthropologists have increasingly become interested in discovering how members of a culture know what to say to whom, when, where, and how, they have started concentrating on discovering how cultural knowledge of appropriate language usage is acquired and how specific cultural patterns of language use could be analyzed.

The theoretical model labeled the 'Ethnography of Speaking' (Hymes 1964, 1972, 1974) can be applied for delineating cultural patterns of language usage. The basic units of analysis are speech community, speech event, and speech act. While the first concept has been much discussed, criticized concerning its usefulness, and modified (see *Speech Community*), the concepts of speech event and speech act have been much more central to this model. The focus of this approach is on linguistic performance and its sociocultural constraints, especially its appropriateness as judged by the participants in specific social interaction.

The components of a speech act (Hymes 1964) are: time and place; participants and their backgrounds in terms of age, sex, education, class/caste, residence, and so on; channel, code, topic, message, and cultural norms of interactions and expectations. Such functions of speech act as expressive, directive, referential, contextual, contact, poetic (stylistic), metalinguistic and metacommunicative have been identified. This theoretical model has been revised over a period of several years (Hymes 1972) and now an acronym SPEAKING represents the components of speech acts, that is, setting, participants, ends, act sequences, keys, instrumentalities, norms of interaction, and

41

genres. Several ethnographic studies have been carried out in the last 25 years applying this framework. They present analytical descriptions of culture-specific speech genres in terms of their components, functions, and norms of appropriateness of usage (Bauman and Sherzer 1974, Philipsen and Carbaugh 1986).

The ethnography of speaking framework is etic in nature. Analyses resulting from its application provide insights only into emic patterns of language usage and rule-governed speech behavior. However, the model has not developed into a general theory of the possible relationship among the various components at the universal level. Part of the problem may be that discerning patterns of language usage involves concrete culture-specific ethnographic information with regard to both the nature and the relationships of components and functions. Such ethnographic data and analyses are not amenable to abstraction for universalization, unlike the situation in structural or generative linguistic theory. Speech genres are cultural-specific constructs dependent on linguistic and sociocultural knowledge.

3.2 Discourse Analysis

Discourse analysis (see *Discourse*), though primarily a field of inquiry in linguistics, has now become multidisciplinary in nature and the object of inquiry may mean different things to sociolinguists, anthropologists, psychologists, and computational linguists, especially those interested in artificial intelligence. The main focus in all such investigations is on the linguistic text with varying degrees of sociocultural context taken into consideration. The basic issue, then, is one of demonstrating how extralinguistic knowledge as reflected in cognitive and/or social structures and independent of communication is brought into the speech situation so as to convey the participants' intentions and purposes in linguistic interaction (Brown and Yule 1983, Coulthard 1985, Gumperz 1982, Sherzer 1987).

It is clear that discourse involves both text and context. The focus, therefore, could be on either or both and in this respect it analyzes, like the ethnography of speaking, language usage. A major problem in discourse analysis is the elusive nature of the object of inquiry. Discourse as a linguistic text constantly emerges and re-emerges, is created and recreated in keeping with the appropriate sociocultural context. Although a discourse text may consist of a single sentence, it is generally assumed that it involves a continuous text consisting of several sentences and could be in the nature of a narrative, dialog, discussion, political speech, question–answer sequence, poetry, verbal duel, magical chant, and the like.

Despite the changing nature of discourse, research has indicated that there are some general properties that characterize most linguistic discourse. Primarily, discourse is interactional or transactional in nature, since one of the basic functions of language is to transmit information, be it factual or propositional. Discourse analysis focuses on what the participants in a social situation must know in order to identify and interpret various types of linguistic utterances such as questions, suggestions, requests, and statements. Discourse is also used for negotiating relationships among participants based on their respective roles, for emphasizing group cohesion and solidarity, for opportunities to take a turn in speaking and expressing one's views, for apologizing or face-saving, for beginning or ending social interaction, and so on. Linguistic discourse, then, is the primary tool for social interaction.

Despite the varied functions of linguistic discourse, analysts consider the concepts of 'coherence' and 'relevance' as crucial for the interpretation of any discourse text. Speakers and listeners both depend on linguistic and nonlinguistic contextual assumptions which are necessary to construct their models of the state of affairs and the events that are described in discourse. In humorous discourse, the goal is to make participants aware that the coherence aimed at in the discourse is other than the one they are likely to understand initially. Since such an interpretation does not suit the overall situation, they are forced to look for another kind of coherence and relevance. The linguistic text has to be sufficiently ambiguous for this to happen, and therein lies the creativity aspect of humor (Apte 1987).

3.2.1 Communicative and Discourse Strategies

Strategies used by individuals in any social interaction involving speech are important in understanding the nature of speech acts. Individuals often attempt to manipulate a social situation to their advantage while remaining within the rule-governed cultural norms of appropriateness. The means of speech available to do this are the totality of distinct language varieties, that is, dialects and styles employed in a community and an individual's linguistic repertoire dependent on his/her ability to use varied registers, styles, dialects and languages, code-switching and code-mixing, and linguistic creativity. These strategies often shape the nature of speech events and determine what form a speech act will take, and constitute a legitimate part of linguistic discourse in social life.

Various discourse strategies used by participants constitute a fundamental aspect of any discourse. Analysts attempt to replicate the comprehension process and interpretation strategies of participants in speech interaction. Such an interpretation relies on grammatical knowledge, and linguistic and extralinguistic presuppositions. Additionally, participants look for coherence and relevance in the linguistic text

and, drawing on their knowledge of the world, attempt to interpret utterances in context by drawing inferences. Contextualizing cues are all-important in such interpretation and both the speaker and listener use them, which makes such cues a major part of discourse strategies.

Gumperz (1982) (see *Gumperz, John J.*) has analyzed linguistic discourses in English between native English speakers in England and South Asian immigrants to England, and between White and Afro-American individuals in the US. In these instances, because they speak the same language, the participants assume a common base in terms of cultural knowledge, presuppositions, and strategies, including contextualization cues. However, as Gumperz has demonstrated, the participants have different sets of extralinguistic knowledge, assumptions, and expectations, leading to misinterpretations. It is evident that lack of cultural knowledge, of shared presuppositions, and of appropriate contextualizing cues can result in miscommunication or no communication at all, despite a shared purely linguistic competence. Tannen (1990) has demonstrated the differences in discourse strategies based on sexual identity. In North American culture, men and women are socialized into using different strategies for participation in interpersonal and social conversation.

Code-switching (see *Code-switching: Overview*) and code-mixing are also important discourse strategies. Code-switching, as the term suggests, involves changing a code in the middle of linguistic discourse, that is, switching from one language, dialect, style, or register to another. Such a strategy may be undertaken by a speaker for a variety of reasons and intentions, such as: belief about the appropriateness of a code to a particular domain and/or situation—called situational code switching; for broaching or discussing a specific topic; for reinforcing a message in terms of solidarity; use of a specific code commensurate with the listener's social background; or simply the lack of mastery over a specific code in contrast to another. Such code-switching is quite common among bi- and multilingual speakers, who may have definite notions as to which language is appropriate for particular domains and/or topics. Code-mixing generally results from inadequate code-switching, so that grammatical and lexical features of more than one code, be it a language or dialect, are juxtaposed within a single sentence. The most common code-mixing is of the lexical type.

3.3 Conversational Analysis

The objectives of conversational analysis (see *Conversation Analysis*) are similar to those of discourse analysis except that the focus is on studying the process *per se* without making any *a priori* assumptions about the social and cultural backgrounds of participants. Thus, conversational analysis is strictly linguistic in nature. Most conversational analysis research has focused on naturally occurring actual conversations in social interactions. The primary goal is to identify, describe, and explain the numerous processes through which participants engaged in conversation create joint meanings (Goodwin 1981, Jefferson 1978, Sacks et al. 1974, Schiffrin 1987, 1988, Tannen 1990).

Such concepts as turn-taking, sequentiality, conversational inference, speech routines, dialogic pairs, and opening and closing conversations are fundamental to conversational analysis. Of these, turn-taking has been considered the most crucial and refers to the ways in which conversation is distributed among two or more participants who take turns at speaking. In many routine conversational interactions two contiguously occurring related utterances are commonly found and are called adjacency pairs. For example, such conversational encounters as, greeting–greeting, question–answer, offer–acceptance/rejection, etc., occur frequently in everyday social interactions and constitute fundamental units of conversational analysis.

3.4 Linguistic and Social Variation

One of the primary objectives of sociolinguistic research has been to investigate linguistic variation as it relates to social variation. While dialectological studies have long focused on linguistic variation, such a focus was primarily on geographical variations in individual phonological and grammatical units within a linguistic community. Sociolinguists have been interested in finding out the relationship between language variation and such biosocial factors as age, sex, race, socioeconomic class, occupation, ethnic identity, whether such relationships are systematic and collective rather than idiosyncratic, and whether they are persistent over time. Another related objective is to discover to what extent the social networks of individual speakers, their notions of correct speech, status and prestige, and their motivations and desire of upward mobility influence their speech. In short, the goal is to discover the structure of variation.

Correlational sociolinguistic studies generally select certain phonological, morphological and/or syntactic variables and discover how their variants are socially distributed, that is, which variants of these variables are used by members of groups with differential class, racial, ethnic, sexual, and age backgrounds. One methodological problem is that some social variables are not amenable to clearcut classification. While it is fairly easy to correlate the occurrences of the variants of a linguistic variable to such factors as sex and age which are easy to categorize, it is difficult to relate linguistic variants to such factors as race and ethnicity which are

subjective in nature. This is also the case to some extent with social class membership.

While the objectives of correlational studies have been in keeping with the broad scope of sociolinguistic inquiry, the process of developing methodology for such studies has been slow and difficult, especially since the emphasis has been on a quantitative approach due to the importance given to such criteria as exactness, methodological rigor and, verifiability. Several early studies which looked at differences within a linguistic community and linked them to social status did not necessarily use quantitative methodology. However, they drew attention to the fact that intralanguage variation carries with it certain social status and positive as well as negative attitudes and cultural values.

The identification by Geertz (1960) of three different styles in Javanese and of their association with elite, merchant, and peasant groups, and the identification by Ferguson (1959) of diglossia (see *Diglossia*), that is, stable existence of high and low speech varieties, among Arabic, Greek, and Tamil language communities in which speakers did not generally accord the status of language proper to the low varieties, but only to the high ones, are examples of linguistic variation as related to sociocultural factors.

However, since the mid-1960s innovative thinking and new methodological strategies have been developed and used successfully in several studies which demonstrated systematic correlation between linguistic and social variables in certain types of speech events (Labov 1966, 1972, Wolfram 1969, Trudgill 1974b). Such criteria as education, occupation, and income have been used to set up social class categories by applying various scaling techniques. Labov's methods in his study of New York speakers (1966) included anonymous observation, sociolinguistic interviews, and participant observation of social groups and networks, and such linguistic data as word lists, reading style, and samples of careful and casual speech from the most formal to the most informal.

The linguistic variables that sociolinguists interested in correlational studies chose to investigate have been primarily phonological, but grammatical variables have also been studied. One of the earliest studies (Fischer 1958) in fact investigated the occurrence of the variants [ɪŋ] and [ɪn] of the English suffix 'ing' in the speech of young children in a New England community. The results showed their systematic distribution as linked to social and personality factors, formality of the situation, and specific verbs used in particular topics in conversation.

There now exist several correlational studies of linguistic and social variables conducted (see *Sociolinguistic Variation*): among English-speaking populations in the USA, England, and Ireland (see discussion and references in Guy 1988; among French-speaking populations in Canada (Sankoff and Cedergren 1971); and among Persian speakers in Iran (Jahangiri 1980). While there is no unanimity regarding the usefulness of the results of these studies and of their impact on linguistic theory of language change, they have enabled sociolinguists to gain some insights into the origins and nature of changes that languages undergo. The nature of linguistic variation as it relates to sociocultural factors is now much better understood. Additionally, these studies have contributed significantly to the refinement of existing methodology and to the development of new methodological techniques in sociolinguistic studies.

It is now generally accepted that linguistic variation is neither random nor confined to the idiosyncracies of individual speakers. Correlational studies show that individual speakers are aware of positive and/or negative societal attitudes towards particular linguistic features; that they try, consciously or unconsciously, to change their speech patterns to acquire the prestige variants of linguistic variables which are often part of the standard variety of a language. Overt societal prestige is thus generated from the top down.

It has also been evident, however, that factors such as group membership and group solidarity can be countervailing forces whereby the negatively perceived linguistic variants may be maintained by individuals. According to Labov they are maintained because of their covert prestige, in that speakers reject linguistic markers of socially prestigious speech and prefer to maintain linguistic features which identify them with their own social groups.

3.4.1 Language and Gender

Among all the research endeavors into linguistic variation, the question receiving the most attention is perhaps that of the relationship between language and gender (see *Gender and Language*; *Gay Language*). This has been an offshoot of the feminist movement and consequent emphasis on women's studies. While in the past differences between men's and women's speech had been noted by linguists, especially in non-Indo–European languages, such studies did not go beyond the goal of mere structural and lexical description of sex-related linguistic differences. There was little attempt to link them to social structure, behavioral patterns, and cultural values.

Lakoff's study in 1973 was instrumental in changing this situation, and since then numerous studies focusing on women's language have been published. Some have attempted to further verify Lakoff's subjective and impressionistic observations (Crosby and Nyquist 1977, Dubois and Crouch 1976). Others

have investigated the causes behind the differences between men's and women's speech, and their conversational strategies, and at least in the USA there has begun a movement to change the nature of what are considered to be sexist expressions. The extent to which the introduction of gender-neutral usages has been influential is reflected in a recent newsletter of the Linguistic Society of America and in publications of the Modern Language Association of America, both of which include guidelines for avoiding sexist language.

Sociolinguistic studies of gender differences demonstrate that men's and women's language is intimately connected to sociocultural patterns which reflect sexual inequality and male dominance in many societies. Men and women are said to grow up in different cultures whereby they develop different communication styles. Until recently, both men and women had accepted this inequality which is generally based on ideal cultural role models for men and women. It is expected that women be modest, submissive, nurturing, and concensus-seeking, while men be aggressive, forthright, dominant, and individualistic. Language differences and conversational strategies of both sexes seem to reflect these cultural values and commensurate behavioral patterns.

Sociolinguistic investigations of the differences in men's and women's communicative styles in North American society (Kramarae 1981, Lakoff 1973, Tannen 1990) seem to suggest that women emphasize indirectness in their speech, say one thing when they mean another, are not forthright in expressing their views, and seem less keen on forcefully expressing themselves in interpersonal interactions or in social situations involving several participants. In conversational strategies, women seem to depend much more on metamessages than do men. A primary cause of miscommunication between men and women in intimate relationships is the lack of understanding about the differences in the conversational strategies used by the sexes (Tannen 1990).

In many societies, cultural values dictate that women do not explicitly refer to or discuss matters relating to sexual activity. They are often constrained from using abusive and/or obscene language or taboo words, and from participating in ritual insults or verbal duels, because such activities may reflect on their moral and sexual character. Additionally, politeness (see *Politeness*) is seen as a positive aspect of women's linguistic and social behavior (Apte 1985: 74–75). In general, then, it appears that there are differential rules for language usage as pertaining to different sexes and that most of the constraints are on women's linguistic performance, which in turn reflects the overall social and political inequality between men and women.

While much of the literature on the relationship between language and gender focuses on English in

the context of North American society (Kramarae 1981, Thorne and Henley 1975), there is a growing interest in looking at sexual differences in language structure and use across cultures (Philips et al. 1987). The implications of such studies are that power relations in society are closely linked to both structure and usage of language (see *Power and Language*; *Critical Sociolinguistics*).

3.4.2 Language and Race

In recent years, the concept of 'race' has come under considerable scrutiny in social science research literature, especially in anthropological writings. The general consensus in anthropology is that racial categories as used in the anthropological publications before 1950 represented a purely descriptive taxonomy. It is now well established that the divisions between people of different races are arbitrary, because the genotypical and phenotypical traits on which they are based cannot be neatly differentiated. Despite this state of affairs in the scientific community, the idea of race is very much alive in the popular mind in most societies. The concept of race is often fused with that of ethnic identity, though other factors such as place of origin, cultural background, religion, and language are also aspects of this. Anthropologists, however, have rejected race as an important factor in defining ethnic groups (Fried 1965, Montagu 1964).

In discussing linguistic variation, sociolinguists have faced a real challenge in refuting popular beliefs concerning the linguistic performance of members of different races, namely, that members of particular races are incapable of learning and speaking a language properly. Earlier anthropologists such as Boas and Sapir made it quite clear that the degree of structural complexity of a language had no relationship with the biological and cultural attributes of its speakers. Yet notions of the existence of primitive languages still persist, as do those of racial inferiority in linguistic competence.

Since the 1960s, the major controversy in the sociolinguistic literature concerning the relationship between language and race has focused on the speech of Americans in the USA. While African-American speech was at one time labeled a corrupt dialectal version of standard American English, and African-Americans were assumed to be incapable of learning the standard variety, considerable research has shown that the African-American speech variety, commonly referred to as Black English (BE), Black English Vernacular (BEV), or African-American Vernacular English (AAVE) in the literature, is a distinct speech variety in its own right. It has even been claimed that BEV cannot be treated as a mere dialect of American English, but, rather, should be recognized as a variety of English comparable to such

others as Australian, South African, South Asian, or West-Indian English. Another important result of this research is the awareness that not all African-Americans speak in the same way, and that there are linguistic variations among different segments of the African-American population in the USA.

Equally important is the fact that linguistic features in which African-American English, differs from standard English are systematic and persistent (Dillard 1972). It has been argued that part of the problem faced by African-American children in the school environment is the insistence by teachers that only the standard variety be used in classrooms. While many African-Americans are quite proficient at code-switching between the standard and their own speech variety, the resurgence of pride in African-American identity has strengthened the use of African-American speech. It has also been shown that African-American children, adolescents, and young men and women are quite capable of presenting arguments in a logical and rational way using their own speech patterns (Baugh 1983, 1988, Labov 1972).

Language socialization, and prejudicial or positive attitudes towards language often have a significant effect on speech. The study by Heath (1983) (see *Heath, Shirley Brice*) of school children in two communities of White and Black populations in South Carolina showed quite distinct language socialization patterns in each of these culturally different communities. Black children seemed to have an innovative and creative way with words, and a playful attitude towards language; they did not hesitate in experimenting with it. Once the teachers became aware of the differences between Black and White children concerning language socialization patterns, they were able to devise innovative techniques to introduce Black children to mainstream language. That African-Americans have a playful and creative attitude towards language has been amply demonstrated by several studies of speech play among them. They seem to have an extensive repertoire of different ways of talking (Kochman 1972).

The controversy regarding the relationship between language and race is by no means settled, and the view that lack of 'proper' usage of language reflects genetically inferior intellectual ability (Jensen 1969) still persists to some degree in the public mind. However, there is increasing awareness in the population at large of the influence of negative racial stereotyping and prejudice on popular views. There is also a growing realization that linguistic differences are not necessarily reflective of racial differences, but, rather, of economic, political, and sociocultural factors and of differential upbringing (see *Code, Sociolinguistic*).

4. Directions for Future Research

Sociolinguistics is such a vigorously growing field of inquiry that it is difficult to predict the directions in which it will develop. It is safe to say that the more culture-specific and cross-cultural studies focusing on many issues related to linguistic variation, language use, and language function are made available in the future, the greater the potential for developing universal sociolinguistic theories pertaining to the numerous issues discussed in this essay. Judging by the plethora of publications that have emerged since the 1960s, the future of sociolinguistic research seems bright.

Multiculturalism and Language
J. R. Edwards

Focusing upon linguistic and cultural contact means focusing upon group identity. It is this sense of 'groupness'—ethnic or national—and the recognition which both underpins and reflects it that constitute the core of the discussion on multiculturalism, a discourse that is essentially sociopsychological and usually emotionally charged. This can be true from either side of group boundaries: linguistic and cultural continuity, for example, can be both a rallying point for members of a beleaguered minority and an irritant (or worse) for those fearful of social balkanization or fissiparous movements. Multiculturalism is an icon for some, an illusion for others. And language—particularly in its symbolic roles, as well as in those communicative ones that link past to present, that bear culture across generations—is in many instances the centerpiece of the multicultural thrust. During and after language shift, it is certainly possible to maintain cultural distinctiveness and the sense of border that is the heart of group definition. However, this is not a viewpoint likely to be endorsed by people who feel themselves at risk of assimilation, nor can it be denied that continuity of language use is a powerful cultural buttress.

The politics of identity—the skeleton, that is to say, which is fleshed out by cultural and linguistic differences, details and demands—is of special current salience. Our age is one of transition, and transitions are often difficult and painful. In the territories of the former Soviet Union, in the increasing western European federalism, in the killing fields of Africa—but also in the struggles of indigenous peoples in North and South America, in the debates about multicultural accommodations in new-world 'receiving' societies (Canada, Australia, the USA)—we see contexts in flux, identities up for re-negotiation, languages in contact or conflict, 'small' cultures attempting to resist larger ones, and so on. It is true that, in some cases, the 'ethnic' factor

in conflict is something of a red herring. The Hutus and the Tutsis of Rwanda essentially share the same culture, religion, and language and, consequently, ethnic difference was not the real nub of the conflict that led to the massacres in 1994. In Africa, Asia and elsewhere, colonialism planted many delayed-action devices, emphasizing and stiffening cultural difference. But even if ethnic or nationalist roots are not, in themselves, causal phenomena (in situations of group friction), their very existence—the fact that they are *there*, the fact that dormant, or even unreal, traditions can be evoked and played upon, the fact that manipulated or selective history can be made to serve current ends—is of considerable importance. In some other cases, matters of language and culture are not only symbolic markers signaling deeper waters, but are more centrally implicated in inter-group conflict. It is not economic deprivation or lack of effective political representation in federal corridors that primarily fuels the sovereignty movement in Quebec—yet its power has come within a hair's breadth of breaking up the country.

Multiculturalism usually implies multilingualism and, at a *de facto* level, they exist in virtually all countries, in very few of which national and state borders are coterminous (see Connor 1978). At a *de jure* level, languages are more often accommodated than are cultures. Still, despite a large number of languages and a small number of states—about 5,000 and 200, respectively—only about a quarter of the world's polities recognize more than one language (and recognition itself rarely implies or reflects equivalent status; see Edwards 1995).

Legislated attention to cultural diversity is rare, and Canada and Australia are virtually alone in having official multicultural policies. The Canadian approach is generally illustrative. Two years after the establishment of linguistic duality (with the Official Languages Act of 1969), a policy of multiculturalism

was announced, and an Act was passed in 1988—the aims were, from the first, to assist cultural groups to develop and to contribute to the larger society, and to help them learn either or both of the two official languages. Further elaboration (as found in the Act) stressed the preservation and enhancement of other languages—but this is supposed to coincide with the strengthening of English and French, too, the national commitment to which is reaffirmed. The Canadian policy demonstrates, then, the generalities employed when cultural maintenance or the continuity of non-official languages is under discussion (the Act talks of enhancing the Canadian 'multicultural heritage'), as opposed to the specificity attaching to the status of legally sanctioned varieties. Unsurprisingly, this package has been seen as rather an empty one; more pointedly, the feasibility of *multi*culturalism within a *bi*lingual framework and the depth, therefore, of real government commitment has been questioned. Of course, reactions to official multiculturalism range very widely, from the mistaken notion that it is a spur to ethnic separatism and an impediment to national unity (perhaps, indeed, to the emergence of some eventual, nonhyphenated *Canadian* identity), to the naïve belief that it enshrines and reflects a general tolerance for diversity— evidence for the moral superiority of the Canadian 'mosaic' over the more southerly 'melting pot.'

But the Canadian policy, for all its generality and its possible interpretations, is more broadly significant as an example of political response to diversity. Liberal democracies are of course obliged by deepest principle to consider multicultural realities—but consideration does not imply uniformity of sensitivity or reaction. In the Canadian approach to multiculturalism, an apparent response at the level of the group, the collectivity, is arguably of such a general nature (and, one should add, is so weakly supported, financially and otherwise) that it represents only a tiny course adjustment to the more traditional liberal stance in which rights are seen to inhere in individuals, a stance broadly descriptive of contemporary western society. So, to the reactions already mentioned, we can add two further interpretations of multicultural policy: it represents only politically opportunistic lip-service to the idea of cultural maintenance (a view which could of course be *endorsed* by the cynical assimilationist); or, it is a genuine response to heterogeneity, but one that is unfortunately flawed in its framing and its application. It need hardly be said that these and other stances are not unique to the Canadian context.

The appropriate democratic response to cultural diversity is of course the underlying issue here. Should there be formal multicultural policies at all and, if so, should they enshrine some level of commitment to group rights? What level? And what

groups? The literature on multiculturalism and its ramifications—pluralist accommodation, the negotiation of identity, the rights of minorities, the obligations of the liberal state, and so on—has only recently turned to such matters. The turn, however, has been significant, and there is now a concern for 'identity' that extends from literature, to the social and political sciences, to philosophy.

In his treatment of 'identity politics,' Taylor invokes the idea of 'recognition' and, more specifically, the politics of equal recognition as fundamental. But this can shade easily into a politics of group difference, in which the uniqueness of group identity is emphasized. It is this, of course, which adherents claim is at risk of being ignored or, worse, assimilated to some overarching majority (the 'cardinal sin against the ideal of authenticity': Taylor 1994: 38). So we arrive at an interesting juncture: the principle of universal equality is stressed but within that, as it were, arise demands for the recognition of distinctiveness. The demands of general respect, on the one hand, and of particularity, on the other, lead to difficulties:

> The reproach the first makes to the second is just that it violates the principle of nondiscrimination. The reproach the second makes to the first is that it negates identity by forcing people into a homogeneous mold that is untrue to them (Taylor 1994: 43).

Bearing in mind the traditional liberal sense that society ought to ensure individual equality but remain neutral as to the desired contents of lives, but aware of the concerns of cultural collectivities (especially, of course, those under threat from powerful neighbors), Taylor argues for a more 'hospitable' liberalism that departs somewhat from this traditional neutrality, for the idea that cultures should be given some means of self-defense, for at least an initial presumption of equal worth—for something, that is, between a cruel homogenization and an ethnocentric self-immurement.

Kymlicka (1995) has also addressed the matter, arguing that it is within the bounds of liberal democracy to provide groups with the means to ensure their cultural continuity—and, where these groups are specially disadvantaged, this may in turn require special attention, perhaps special rights. In this connection he defends treatment differentiating between indigenous minorities and immigrant groups. Kymlicka (see also 1998) has concerned himself particularly with the Canadian context, suggesting that the multicultural policy is—or could be—an effective instrument. It is interesting (given what I have noted above) that he repeatedly points out that this policy, now to be understood as a vehicle for the provision of group rights, is, after all, no real threat to the *status quo*. Diversity will be subject to reasonable limits, and existing conceptions

of rights, freedoms and human dignity will not be overturned.

It is impossible to analyze here the rich detail of these sorts of arguments (or, indeed, to note the criticism they have elicited). But they are the ones we now need, since they confront the underpinnings of multiculturalism and may thus lead to useful generalities applicable across contexts. A great deal of the literature has, for too long, consisted of special pleading for one group or another, under the guise of a broad concern for pluralist accommodation. A more profound assessment of multiculturalism will necessarily involve its linguistic components, and that is why I have emphasized the former in this brief discussion. It is of course possible to attend to language *per se* without much concern for its cultural foundations. But an instrumental approach omits the essence of the matter here: the interweaving of language as a strand in the larger fabric, as part of a broad concern with identity and belonging.

Pragmatics and Sociolinguistics
J. L. Mey

1. Introduction
1.1 The Origins of Pragmatics
Among pragmaticians, there seems to be no agreement as to how to do pragmatics, nor as to what pragmatics is, nor how to define it, nor even as to what pragmatics is *not* (see Mey 1989). Pragmatics appears to be the first, historically motivated approach towards a societal relevant practice of linguistics. Naturally, such an approach does not originate *ex nihilo*: at least three (and perhaps four) developments, or developmental tendencies, can be distinguished, which together (in unison or in counterpoint) have made pragmatics into what it was in the early 1990s.

1.1.1 The 'Antisyntactic' Tendency
This tendency can be seen as a reaction to the 'syntacticism' of the Chomskyan School of linguistics, whereby all of linguistic science (including phonology and semantics) was supposed to fit into the syntactic framework. Linguists such as George Lakoff and John Robert ('Haj') Ross were the first to protest against this syntactic straitjacket; of the numerous alternative 'frameworks' proposed in the late 1960s (such as 'Generative Semantics'), none was truly pragmatic in orientation. Furthermore, these alternatives were (naturally as well as geographically) limited to North America; they never caught on in Europe.

1.1.2 The 'Social-Critical' Tendency
This tendency had its origin and heyday in Europe (starting independently in the UK, in Germany, and in Scandinavia, and spreading over most of the continent and later also outside, especially to Australia). Characteristic of this tendency is the need for a socially useful science of language, together with a wish to leave the narrow perspectives of the 'single discipline' behind. Not surprisingly, the effects of language on people's lives, especially in situations of unequal societal power, attracted the interest of these early pragmaticians (such as Basil Bernstein in England, or Dieter Wunderlich in (the then West) Germany). The impact of their work was felt throughout the 1970s and far into the 1980s (for more on this topic, especially Bernstein's work, see Sect. 2.6; also see Wunderlich 1970 and *Critical Sociolinguistics*; *Critical Language Awareness*).

1.1.3 The Philosophical Tradition
Originating in the British critical tradition of language investigation (illustrated by names such as Bertrand Russell, Ludwig Wittgenstein, John L. Austin, Gilbert Ryle, and others of the school of 'ordinary language philosophy,' and many more), this tendency was virtually unknown outside the UK until the late 1960s. It was only after the publication of Austin's student John Searle's landmark work *Speech Acts* (1969; see *Speech Act Theory: Overview*) that the first inroads into what later became known as pragmatic territory were made by Chomsky's rebellious students. To their great surprise, they found the region populated and partly cultivated by people such as those mentioned above (to use Geoffrey Leech's colorful image):

> When linguistic pioneers such as Ross and Lakoff staked claim in pragmatics in the late 1960s, they encountered

there an indigenous breed of philosophers of language who had been quietly cultivating the territory for some time. In fact, the more lasting influences on modern pragmatics have been those of philosophers; notably, in recent years, Austin (1962), Searle (1969), and Grice (1975) (Leech 1983: 2).

1.1.4 The Ethnomethodological Tradition

Finally, mention must be made of a 'Johnny-come-lately' (but a rather influential one): the so-called ethnomethodological tradition. In this tradition, the emphasis had always been on communication rather than on grammar; how people got their messages across was considered more important than the ways in which they constructed their sentences, or whether or not their utterances were syntactically correct or logically consistent.

The ethnomethodologists (see *Ethnomethodology*) were clearly, in this respect as in many others, a different breed from the linguists and the philosophers (including those whose main interests had avowedly been 'ordinary' or 'everyday' language). The notion of language as the object of a scientific investigation that will make possible the description, classification, and definition of language phenomena in an abstract way, with the aid of objective correctness criteria (interpreted as providing univocal answers to questions such as whether an utterance is 'in the language' or not, à la Chomsky), is never taken seriously in ethnomethodology. Conversely, most of the linguists of this early period never took the ethnomethodologists and their results, especially in the domain of conversation analysis (see *Conversation Analysis*), seriously either.

Saying that this research tradition came late in the day, relative to the other tendencies, is of course itself a relative assertion-relative, to be exact, to the point of time at which the linguists first started to recognize the ethnomethodologists, their methods, and their results. While the precise 'moment of truth' cannot be established, it seems safe to say that from the mid-1970s, references to ethnomethodological research start turning up in the linguistic literature. By the early 1980s, the ethnomethodologists are firmly ensconced in pragmatics; thus, Levinson devotes roughly a quarter of the entire text of his book *Pragmatics* (1983) to their ideas and techniques (Chap. 6: 'Conversational Structure'). Names such as Harvey Sacks (see *Sacks, Harvey*), Emanuel Schegloff (see *Schlegoff, Emanuel*), and Gail Jefferson became household words in linguistic circles after the publication of their groundbreaking article in the prestigious linguistics journal *Language* in 1974; their style of investigation (often referred to by the nickname of the 'Santa Barbara School') has also been widely adopted in other research environments.

Still, even in the 1990s, many (mostly pure-theory oriented) linguists deplored this intrusion into their discipline by methods that are not strictly linguistically accountable, inasmuch as they derived their proper object from sciences such as ethnology and anthropology.

2. Societal Pragmatics

2.1 Linguistics and Society

The question of societal pragmatics is intimately connected with the relationship between linguistics as a 'pure' science and the practice of linguistics as applied to what people use their language for, to 'what they do with their words.' Traditionally, in linguistics this split reflects itself in the cleavage of the discipline into two major branches that do not seem to speak to each other: *theoretical* linguistics and *applied* linguistics.

Traditionally, too, the former kind of linguistics has carried all the prestige of a 'real' (some would say 'hard') science, whereas the latter was considered the soft underbelly of linguistics, prone to all sorts of outside and irrelevant, because 'extralinguistic,' kinds of influences.

It has been one of the hallmarks of pragmatics, ever since its inception as an independent field of study within linguistics, to want to do away with this split. Pragmatics admonishes the linguistic 'scientists' that they should take the users of language more seriously, as they, after all, provide the bread and butter of linguistic theorizing, and it tells the practical workers in the 'applied' fields of sociolinguistics, such as language teaching, remedial linguistics, and the like (see *Applied Linguistics and Sociolinguistics*), that they need to integrate their practical endeavors toward a better use of language with a theory of language use. However, despite much goodwill, many efforts, and a generally propitious climate for such endeavors, the 'unification' of linguistics is not something that is easily achieved. Pragmatics will probably, for a long time to come, be considered by many linguists not so much a 'science' in its own right as an aspect (albeit a valuable one) of, and a complement (albeit a necessary one) to, traditional linguistics.

The *user* aspect has from the very beginning been the mainstay of pragmatics. Already in the very first mentions of the term (such as by Charles Morris (1938), following earlier work by Charles S. Peirce), the term 'pragmatics' is closely tied to the user of language; pragmatics is thus clearly distinguished from, even opposed to, both syntax and semantics, as isolated disciplines.

However, the users not only had to be discovered they also had to be positioned where they belonged, in their *societal context*, 'context' to be taken here not only as the developmental basis for their activity as

language users but as the main conditioning factor that made that activity possible. The question of how people acquire their language turned out to be more of a social than a developmental problem that could only be discussed in a strictly psychological environment (as had been hypothesized earlier). A societal window on language acquisition and language use was opened, and pragmaticists soon found themselves joining hands with sociologists and educationalists that had been working in these areas for many years.

The question naturally arises as to what distinguishes pragmatics from those neighboring disciplines (among which several others could have been mentioned). The answer is that pragmatics focuses on the user and his or her *conditions* of language use. By this is meant not only that the user is considered as being in possession of certain language facilities (either innate, as some have postulated, or acquired, or a combination of both) which have to be developed through a process of individual growth and evolution, but, more specifically, that there are certain societal factors that influence the development and use of language, both in the acquisition stage and in usage itself (see *Bilingualism and Language Acquisition*; *Language Change and Language Acquisition*).

Whereas earlier (according to mainstream, especially faculty psychology) the use of speech was said to develop only if it was stimulated during the so-called psychologically 'sensitive' period, it has become somewhat of a pragmatic tenet that such stimulation is social more than anything else. This entails that the social conditions for language use are 'built in,' so to say, to the very foundation of language acquisition and use; but also, that such conditions are difficult to detect and determine as to their exact effect. The results of linguistic development in very early life only become evident much later, when young people enter the first stages of their formal education by joining the school system.

It is therefore not surprising that some of the earliest research interests of a truly pragmatic nature concentrated precisely on the problems of school environment versus home environment. A positive correlation could be established between children's school performance and their social status; school achievement is in important respects dependent on the learner's earlier development in the home. White middle-class children, as a whole, could be shown to be significantly better school performers than their peers from lower strata of society, that is, from nonwhite and, in general, non-mainstream environments. (The name of Basil Bernstein is inextricably bound up with this important research, even though later workers came to have a more critical view of his conclusions, see below, Sect. 2.6.)

The case of the young person's school achievement is a good illustration of what pragmatics is really about, because it very clearly demonstrates why the pragmatic pattern of thinking originally met with such resistance, and why the earliest impulses to pragmatic research had to come from the outside, so to speak; from the ranks not of linguists, but of educationalists and sociologists. The core of the matter here is that the pragmatic determiners are nearly always totally hidden: one has to postulate them almost without any regard to initial plausibility. Social theory, at least as it was practiced until the mid-1960s, had no explanation to offer for its own statistical results. It was not until the hidden conditions of societal structure and domination were brought out into the open that certain pragmatic features could be identified as important for language use. One of the most crucial of these turned out to be the question of the 'ownership' of cultural goods, and how this ownership was administered through various patterns of 'hegemony' (a term originally due to the Italian Marxist theoretician and linguist Antonio Gramsci), in cultural as in other respects (see *Hegemony*).

The following subsections deal with some of these hidden assumptions by playing some of the characteristic themes, all orchestrated as variations on the main theme: 'Whose language are we speaking, when we use "*our*" language?' (see Mey 1985).

2.2 Language in Education: A Privileged Matter

'Morals are for the rich,' Bertolt Brecht used to say, echoing an earlier saying by Georg Büchner (Woyzeck 1838). With a slight variation on this dictum, it could be said that education is only for those who can afford it. Here, one must consider not only the prohibitively high costs of education in the so-called free enterprise system (at the beginning of the 1990s, tuition costs for US private universities ranged from $14,000 to over $20,000 a year; source: *Daily Northwesterner*, January 10, 1991), but also the affordances having to do with coming from the right social background. The same classes that have established the institutions of higher education have also been material in structuring that education and organizing their curricula; and here one is faced with a self-perpetuating, co-opting system that favors those who are most similar to itself—*par nobis*, as the expression used to be.

One of the requirements for those who aspire to participate in any college or university program is to pass the appropriate tests. Characteristically, these tests are geared to the values of the white, middle-class, male-dominated segments of society; minority students typically do less well on these tests, as is also the case with foreigners. It is not uncommon to observe a foreign student who performs relatively well on the mathematical parts of the GRE (the

'Graduate Record Examination,' a prerequisite to entering graduate school), but who almost fails the verbal part. This alone should induce a healthy skepticism toward the value of such testing as a whole, and draw attention to the part that language plays in devising and administering the test.

At stake here is, among other things, what many educational researchers have dubbed the 'hidden curriculum.' Schools are not only supposed to mediate a professional subject matter through their teaching; equally important are the attitudes and beliefs that are fostered and reinforced through the educational institutions. If one asks what these attitudes are about, one has to go back once more to the question of societal *power*, raised earlier: the prevalent attitudes reflect the attitudes of the powerful segments of society, and are (implicitly or explicitly) geared toward perpetuating the possession of that power among the ruling classes (see Mey 2000: 291–297; *Power and Language*; *Symbolic Power and Language*).

This means, with respect to language, that those people who are able to decide what language can be deemed acceptable, which uses of language should be furthered and encouraged, and which demoted and discouraged, are in a position of power and hence can control the future of whole segments of the population by controlling their actual language behavior.

The classic case of this linguistic *oppression* (as it is called) is that of 'low' versus 'high' prestige dialects of one and the same language, or that of 'pidgin' versus 'standard' languages, where pidgins are considered to be mere deteriorated variants of some higher entity called 'the' language (see *Pidgins and Creoles: An Overview*; *Diglossia*). Gross cases of oppressive linguistic behavior control include the total or partial criminalization of local or vernacular idioms, as in the case of the 'Basque stick' (a punitive device used in the schools of the Basque lands, by which pupils were forced to carry a stick on their outstretched arms as punishment for having used a Basque word or expression, to be relieved only by the next sinner in line; cf. Mey 1985: 27).

In a more profound sense, the question can be asked 'whose language' is the controlling norm and guideline for people's linguistic behavior. This question boils down to asking whose behavior is to be the standard of language use, and what aims such a use should set for itself. Such questions can be answered by referring back to Brecht, as quoted at the beginning of this section. If morals are indeed for the rich, moral behavior is something that one should be able to afford (but, as a rule cannot). However, by appealing to some universally valid laws of justice and equity (which are strictly valid only under idealized circumstances, in a so-called perfect but nowhere existing society of the Utopian kind), the rich are allowed to get away with corruption and

embezzlement, while the sheep thief and the poacher are strung up: 'One man can steal a horse and another cannot look over the fence' (cf. Brecht and Dudov 1932).

What is happening here is not only oppression, as defined above; it might also be called linguistic *repression*, a term covering the subtle but ever so pernicious form of social control through language, as characterized above (see Mey 1985: 26; the distinction between 'oppression' and 'suppression' is originally due to Pateman 1980). The concept of repression plays an important role in defining and describing some pragmatic paradoxes that arise in late twentieth-century pedagogical thinking: either the student is considered to be a completely passive receptacle for the ideas and knowledge to be imparted by the teacher—the 'banking' concept, as Freire has aptly called it (e.g., Freire 1973, Freire and Macedo 1987: xvi)—or the students are supposed to be in the possession of exactly those qualifications, as prerequisites to learning, that the teaching is supposed to imbue them with. In either case, the underprivileged student is doomed to come out a loser: either he/she enters the 'rat race' on the ruling classes' premises (and obtains the privilege of membership in the rat club), or he/she never makes it in society, owing to an underprivileged start in life.

2.3 Other Social Contexts

Even though the educational system is perhaps the most obvious instance of the unequal distribution of social privilege, as it reflects itself in and is perpetuated through language, it is by no means the only one. Among the cases of linguistic repression that have attracted most attention are the language of the media (see *Media Language and Communication*) and the medical interview (see *Doctor–Patient Language*; *Medical Language*). In both these cases, hidden presuppositions of the same kind as the ones characterized above are to be found.

The French sociolinguist Michèle Lacoste has, in a thoughtful study (Lacoste 1981), drawn attention to the fact that the doctor-patient interview, despite its obvious usefulness and even necessity, sins gravely by way of linguistic repression. What the physician allows the patient to tell him or her, is not what the patient wants to tell, or is able to tell, but rather what in the institutionalized 'discourse' of the doctor-patient relationship is *pragmatically* possible. That is to say, the pragmatic presuppositions that govern the use of language in this particular case are those that are defined by the social institution of the interview in which the interaction between doctor and patient takes place.

For the patient, talking in this way has nothing to do with expressing oneself or manifesting one's problems; it is more akin to filling out a form with preset categories of questions and answers, or to

submitting oneself to a 'multiple choice' type of examination.

In Lacoste's case, an elderly lady is complaining to her doctor about pains in her spleen. However, the doctor denies this, and instead locates the pains in the lady's stomach. When the patient repeatedly and rather indignantly rejects this suggestion on the grounds that it is *her* body, and that she, if anyone, must be familiar with her own pains, the doctor cuts her off abruptly by saying that she does not even know what a spleen is, even less where it is located in the body.

This example shows two things: for one, the mere knowledge of a linguistic expression in medical terminology (such as 'spleen') and the ability to use it correctly are worth nothing, if the pragmatic preconditions for such a use are not met. The old lady's voice is not heard because she does not possess the necessary societal standing and clout to make her understood.

The other point to be made in this connection is that the linguistic repression, which is taking place, has some very dangerous side effects. The powerlessness of the repressed can easily turn into self-incrimination (by which the powerless attribute their lack of societal value to factors such as fate, God's will, their predestined stance in society ('know your place'), their own lack of capability and potential, and so on). Or else it results in resignation, as happens in the case of the old lady, who ends up saying: 'Whatever you say, doctor'—thereby possibly exposing herself to the risk of a faulty diagnosis, with all its concomitant dangers both to herself (as a patient) and to the physician (as the potential target of a malpractice suit). Clearly, what is needed here is some form of technique or strategy aimed at providing appropriate aid to the societally and linguistically repressed; more on this in Sect. 2.6.

Summing up, then, the case of the medical interview is a clear example of institutionalized discourse in which the value of the individual's linguistic expression is measured strictly by the place that he or she has in the system. Only utterances which meet the criteria of the official discourse are allowed, and indeed registered; others are either rejected or construed as symptoms of (physical or mental) illness, lack of knowledge or even intelligence, and in general of dependent or inferior status. Erving Goffman remarks, much to the point (his observation has primarily to do with mental institutions, but applies to all sorts of institutional discourses; see *Discourse*):

> Mental patients can find themselves in a special bind. To get out of the hospital, or to ease their life within it, they must show acceptance of the place accorded them, and the place accorded them is to support the occupational role of those who appear to force this bargain. (Goffman 1961: 386)

2.4 Language and Manipulation

Goffman's 'special bind' is a particularly clear case of what can be called manipulation, understood as making people behave in a certain way without their knowing why, and perhaps even against their best interests and wishes. Most often, the instrument of manipulation is language—hence the notions of linguistic manipulation and *manipulatory language*. The latter can be defined as the successful hiding (also called 'veiling'; see Mey 1985) of societal oppression by means of language (see *Manipulation*).

A case in point is the professional manipulation in psychiatric environments of schizophrenic patients' speech ('schizophrenese') and its classification as a 'nonlanguage,' that is, a symptom (so-called 'schizophasia') rather than a means of communication. To see this, consider the following two analogical cases.

Suppose that a political prisoner complains to his legal counsel about his letters being opened. Such a complaint makes sense in the context; the prisoner may not be successful in stopping the guards' practice of letter opening, but his utterance 'They are opening my mail' is at least taken seriously.

Not so with the psychiatric patient. The same utterance, in a psychiatric institutional context, is registered as a schizophrenic symptom, proving that the person who utters the sentence is duly and properly a resident of the State Hospital. The patient, by complaining about his or her letters being opened, has furnished conclusive proof of the fact that he or she is not normal, hence has no right to complain. So, ironically, and in accordance with Goffman's observation quoted above, the only correct way of complaining is not to complain; which of course is sheer madness, and proves the point of the patient's being committed.

But it is not necessary to go as far as the psychiatric institutions to find examples of linguistic manipulation. Consider the following. Suppose I am looking for a job. I tell myself that I must make a good impression on my potential future employer; I put on my best suit and tie, and go to the interview in the hope that he will 'give me the job.' Now, I may not be so lucky: the employer may tell me that the job has been 'taken'; somebody else 'got it.' That means they 'have no work' for me, and so on and so forth. In this linguistic universe, employers give, and employees take, viz., jobs. Such is our language.

In real life, however, a totally different picture emerges: it is the employer who takes the employee's labor and converts it to his own profit. The employee gives his or her labor power to the employer, in exchange for a salary offered; but there is one big catch: the wages, although they are called 'fair' and are arrived at in 'free' negotiation, represent a form of societal oppression. The employer knows that he must make the employee accept less than the value of

his or her labor, or else there would not be any profits. The wages are not the equivalent of a certain amount of work: rather, they represent a period of time during which the employer is entitled to press all the labor out of the employee that he possibly can. Wages express the market relation between labor power as a commodity, and whatever else is bought and sold in the marketplace; hence the wages can be called 'fair' only in the sense that they reproduce the market laws, and not by their equitable representation of a certain amount of work.

In this case, too, the language that people use hides the real state of affairs: and thus people can be manipulated into doing whatever the powerful in society (such as employers and doctors) tell them to do. This is what the case of the medical/psychiatric consultation and the job interview have in common.

Somebody might object and say that the worker is not *obliged* to take the employment: an employee is a free agent, and can refuse the employer's offer, and also give notice at any time. However, the very expression of this idea is again a case of manipulatory language use: since a linguistic relation exists between the two nouns, *employer* and *employee*, being respectively active and passive, one is led to believe that the relation between the two 'bearers' of those names is equally symmetrical. The employer is at one end of the employment relation, the employee at the other, but basically it is the same relationship, only in inverse directions. The employer employs the employee; the employee is employed by the employer. Even the language shows us that this is a fair, symmetrical deal.

However, what the language does not tell, and this is the catch, is which of the two is the powerful one in the relationship. The employer is the one who has the sole right to employ or not to employ. Conversely, for the employee there is no right to be employed, which shows where the true power in this situation lies, despite the superficial linguistic symmetry of the employment relation and its manipulatory potential (see *Manipulation*).

2.5 Wording the World

Researchers have paid much attention to language as a means of 'seeing' the world. In well-known studies, Lakoff and Johnson (1980) and Lakoff (1987) have investigated the importance of metaphor as one way of realizing this 'wording.'

Metaphorical wording is different from the classical, referential view of language according to which words are thought of as 'labeling' things in the 'real' world. Metaphors express a way of conceptualizing, of seeing and understanding one's surroundings; in other words, metaphors contribute to one's *mental* model of the world. Because the metaphors of a language community remain more or less stable across historical stages and dialectal differences, they

are of prime importance in securing the continuity, and continued understanding, of language and culture among people.

While one may disagree with some aspects of this view of metaphor, it is certain that understanding the common, metaphorical use of language is essential for an understanding of how people communicate, despite differences in class, culture, and religion, across geographical distances and even across languages. The study of metaphors may thus be one of the keys to solving problems in foreign language understanding and acquisition.

However, the view of metaphor as the only way to understand human cognitive capability is too restrictive. True, metaphors are ways of wording the world. But this wording, in order to obtain the true pragmatic significance that it is usually assigned, should include and respect its own context (see *Context*), because after all, the contexts of people's lives determine what metaphors are available and what their wordings are going to be. An uncritical understanding of metaphor, especially as manifested in a purely descriptive way of dealing with the issue ('Look and describe, but ask no questions') is not only wrong, but downright dangerous from a pragmatic point of view (Mey 1985: 223). And even if our metaphors cannot provide all the answers, pragmatic questions still have to be asked. As an illustration, consider the following.

Lakoff and Johnson routinely assign the female human person to the metaphorical 'low' position, whereas the corresponding 'high' is taken up by the male; this happens about 10 times in the course of one and a half pages (1980: 15–6). Clearly, some explanation has to be found for this curious phenomenon, and it seems reasonable to assume that the authors' particular wording (that is, their choice of metaphors) has a lot to do with the way in which society is structured: men on top, women at the bottom of the 'power pyramid.'

The point here is not to move directly from one 'universe' to another (viz., from the universe of power to the universe of language), but to understand that the way in which people see the world is dependent on the way in which they metaphorically *structure* the world, and that, vice versa, the way in which people see the world as a coherent, metaphorical structure helps them to deal with the world. Put in another way, metaphors are not only ways of solving problems: they may be, and in a deeper sense, ways of *setting* the problems. As Schön remarks, in an important earlier study,

> When we examine the problem-setting stories told by the analysts and practitioners of social policy, it becomes apparent that the framing of problems often depends upon metaphors underlying the stories, which generate problem setting and set the directions of problem solving. (1979: 255)

There is, in other words, a dialectic movement that goes from word to world and from world to word. Neither movement is prior to the other, logically. Ontologically, both movements arise at the same time in the history of human development. In particular, as regards the individual human's development, the child, in acquiring language, is exposed to 'worlding' at the same time as it begins its wording process; one cannot postulate any general, ontological priority of the world as entailing an epistemological or linguistic priority. As Franck and Treichler remark,

> [it can be] argue[d] that language constructs as well as reflects culture. Language thus no longer serves as the transparent vehicle of content or as the simple reflection of reality but itself participates in how that content and reality are formed, apprehended, expressed, and transformed. (1989: 3)

In order to determine what a particular wording is worth, therefore, one has to investigate the conditions of use that are prevalent in the context of the wording. As for metaphors, the question needs to be asked what kind of 'seeing' a metaphor represents, and in what way this 'seeing' affects one's thinking or determines a particular mind-set (for which it was developed in the first place, in all likelihood).

The consequences of this view of wording are that one cannot understand one's interlocutors unless one has a good grasp of their word-and-world context (which includes, but is not limited to, metaphoring). That is, in order to understand another person's wording, the language user has to participate in his or her contexts, to word the world with him or her. Thus, the pragmatic view of language (and, in general, of all societal activity; cf. the quote from Schön (1979) above) demands a 'sympathetic' understanding, as a practice of 'co-wording', in solidarity with the context. To understand an utterance, the language user would ideally have to be able to say it her/himself, in the context of her/his conversational partners—which, after all, is not more than is generally expected of interlocutors in any good conversation. Language-in-use (and in particular, the use of metaphor) is therefore at the same time a necessary instrument of cognition and the expression of that cognition itself. It is a user's language, a user's pragmatic precondition to understanding their context, and to being understood in and through that context (which includes other language users).

2.6 Pragmatics and the Social Struggle

The growing interest in pragmatics as a user-oriented science of language naturally leads to the question of the sense in which pragmatics is *useful* to the users. In particular, given the fact that a sizable portion of the users of any language are 'underprivileged' in their relation to language, and are so, on a deeper level, because of their underprivileged position in society, it seems only reasonable to assume that an insight into the causes of societal underprivilege could trigger a renewed insight into the role of language in social processes, and that, vice versa, a renewed consciousness of language use as the expression of social inequalities could result in what is often called an 'emancipatory' language use.

The first efforts at establishing 'remedial' programs of language training date back to the 1960s, when the so-called 'Head Start' programs endeavored to give underprivileged children from US urban ghettos a chance to keep up with their white, suburban peers by teaching them the extra skills (in particular, language capabilities) that they needed to follow the regular curriculum. The results of these programs, if there were any, usually did not last, because they concentrated on the pure transfer of skills, without any connection to the contexts in which these skills were going to be used, or to the real reasons for the lack of culture and educational privilege: the societal context of the children in question.

The insights that resulted from Basil Bernstein's (1971–90) work with underprivileged children came to serve as guidelines for much of western (European) sociolinguistic and pragmatically inspired research in the 1970s. The terminology that Bernstein developed (in particular, his distinction between an 'elaborated' and a 'restricted' code; see *Code, Sociolinguistic*) was, for a decade or so, dominant in the discourse of emancipatory linguistics (see *Bernstein, Basil*).

Briefly, according to Bernstein, lower-class children, by virtue of their social origin, do not have access to the 'elaborated' linguistic code that is used in schoolteaching. These children, being native speakers of a 'restricted' code, cannot identify with the school language (which simply is not theirs). Therefore, their school achievements stay significantly below those of the other children, who are dealing with the school's 'elaborated' code as a matter of course, since they have been exposed to that code all their lives.

For all its good intentions, Bernstein's solutions to the problem of selective, deficient school instruction did not yield the desired results. For one thing, he focused exclusively on the formal (morphological, syntactic, etc.) aspects of the 'codes', rather than on matters of content and how that content was transmitted. Also, he did not pay explicit attention to the societal background of his codes, except as descriptive scaffolding and motivational support. But on the whole, and from a general sociolinguistic standpoint, one can safely say that Bernstein's notion of the societal context, especially as this concept is manifested in his theory of social stratification, despite all its weaknesses, was significantly more relevant than the class analyses practiced by the majority of his contemporary American and earlier

European colleagues (such 'analyses' mainly consisted in setting up levels of social standing depending on how much money people made, or how often they went to the theater or concert hall, and so on; see Mey 2000: 293–7, *Social Class*).

The question now is whether, in the face of these failed efforts to apply the findings of linguistics to the problems of society, there can be any hopes of practicing pragmatics in the sense of what is so hopefully called 'emancipatory' linguistics.

The answer to that question, of course, depends to a great extent on what is understood by 'emancipation.' If that concept is understood as the elimination of social injustice, as getting rid of the 'bonds' that are inherent in the very word 'emancipation,' then language is not the tool to use. However, if the focus is placed on the *consciousness* of the bondage that is instrumental in creating and maintaining the divisions in society, between haves and have-nots, between rich and poor, between male and female, young and old, and so on, then there are many opportunities for pragmatic linguists to step into the fray and contribute positively to the outcome of the social struggles. The way to do this is for linguists to stay linguists, while orienting themselves toward the pragmatic aspects of their science that is, focusing on the users. The question is thus simply how a 'raised-consciousness' linguistics can contribute to making the users more aware of the language they are using, and in particular, how it can make the under-privileged users 'transcend' the boundaries of their underprivileged ('restricted') use without having them buy into the myths and fantasies of the privileged classes. And vice versa, how the privileged users' consciousness can be raised, so that they no longer consider the privileges of their position as natural and uncontroversial, societally speaking.

Some of the best illustrations of the potential of this (admittedly modest) approach are the results that have been obtained on since at least the 1960s (see *Gender and Language*). Of course, the mere substitution of a combined pronoun such as *he/she* for the supposedly 'generic' *he* (understood as the assertion of '[t]raditional grammars ... that the word *man* functions ... to encompass human beings of both sexes'; Frank and Treichler 1989: 3) does not, in and by itself, change anything in the conditions of society that underprivilege its female members. But if it is true, as McConnell-Ginet says (1989), that 'earlier feminist research has established that *he*, no matter what its user intends, is not unproblematically interpreted as generic, and the consequent shift in the community's beliefs about how *he* is interpreted has influenced what one can intend the pronoun to convey,' then it is also permissible to use this example as one of the areas in which emancipatory linguistics has actually been successful, albeit to a modest

degree, that is, by establishing a whole new code for the use of pronouns in English-pronouns that reflect the growing consciousness of women's presence in society, but that at the same time, and with apparent success, change the ways in which society's members (both female and male) speak, write, and think about women, treat women, and interact with women. As examples, compare the growing number of journals that subscribe to guidelines for 'nonsexist' use of language promulgated and adopted by various scientific societies and journals (such as the American Psychological Association, the Modern Language Association of America, the Linguistic Society of America, and their respective journals).

Language, in McConnell-Ginet's words, 'matters so much precisely because so little matter is attached to it; meanings are not given but must be produced and reproduced, negotiated in situated contexts of communication (1989: 49),' that is, between the users of language themselves in their social and communicative relations, in people's *pragmatic* interaction in and through *linguistic* structures.

Prescriptive and Descriptive Grammar
C. Cullen

Linguistics involves both the writing of grammars and the specification of rules. Therefore it is important to distinguish between the descriptive grammars that linguists are interested in and the prescriptive grammars and grammar rules that people may be more familiar with. Many linguistics courses and elementary textbooks such as Fromkin and Rodman (1997) and Lyons (1981) present the distinction early on so that the nonprescriptive nature of linguistic rules can then be assumed.

Linguists write rules and grammars to provide detailed and accurate descriptions of the knowledge that speakers have of their language. Linguists' rules are statements about what people do in the language, not regulations for what they should do. In this sense, the linguist's use of the word 'rule' is rather like the scientist's use of the word 'law.' The Law of Gravity does not say that objects should/must/ought to fall to the ground, but that objects *do* fall to the ground.

As it happens, much of the time, the linguists' descriptive rules do not conflict with any prescriptive conventions. For instance, when a linguist says that an English Noun Phrase can be made up of a Determiner (such as 'the') followed by an adjective (such as 'red' or 'big') followed by a noun (such as 'bus' or 'book'), the description is both accurate—a good reflection of the knowledge of native speakers of the language—and inoffensive. Even the most opinionated prescriptivist will accept that all of the following phrases are grammatical in English: 'the big bus, the big book, the red bus, the red book.'

But in other situations there may be a difference between descriptive output—rules that show the regular patterns of sentences in a language—and prescriptive conventions. In such cases, it is particularly important to realize that the linguist's interest is in description rather than prescription. For instance,

in most dialects of English a normal and grammatical response to the question 'Who's that?' would be 'It's me,' and a 'descriptive' rule could be written by the linguist for the structure of 'It's me.' However, a common 'prescriptive' rule would say that 'It's me' is bad English (or ungrammatical, in a popular sense) and should be disallowed. The rule would further prescribe that the correct way in which to answer the question 'Who's that?' is to say 'It's I.'

Prescriptive rules are sometimes taught to people in school, sometimes passed on by other speakers, and sometimes found in writers' manuals containing recommendations for clear expression or correct usage. The origins of prescriptive rules vary: some are based on misleading analogies between the grammar of, for example, English and the grammar of some other (often Classical) language or languages. The prescriptive rule forbidding the sentence 'It's me,' for instance, could be justified by the prescriptivist saying that copula 'is' should be followed by a nominative form, not by an accusative form such as 'me,' on analogy with a rule of Latin. No such rule seems to be genuinely operational in early twenty-first-century English.

Some prescriptive rules are rationalized on logical grounds. A common prescriptive rule forbids double negation, which linguists recognize as a grammatical structure in many dialects, and gives logic as the grounds for the prohibition. 'I didn't do nothing' would be described by a linguist's rule if it was grammatical in the variety being studied. It would be rejected by the prescriptivist, who would say that 'I didn't do nothing' could only be used to mean 'I did something' because 'two negatives make a positive.' Now, it *is* true that in logic two negatives make a positive, but it is *not* true in most varieties of English that 'I didn't do nothing' has always to mean 'I did something.' A linguistic description of English will be

based on speakers' knowledge of their language, not on the knowledge of logicians.

The descriptive rules that linguists produce reveal how language is, not just how—because of logic or analogy—it has been agreed it should be. Because the linguists' rules reflect speakers' knowledge, they will vary from the description of one regional or social variety to another. For instance, there will need to be a rule for some varieties of English that describes sequences of modal verbs, as in the sentence 'My daughter may can do that.' For other varieties, sequences of modals do not occur and the descriptive rule will be different. Similarly, 'ain't' will be the grammatical negative occurring in sentences like 'I ain't going home this week' in some varieties of English, while 'I'm not' will be the grammatical form in other varieties.

Having descriptive rules provides recognition of the linguistic equality of all varieties: their shared regularity, their equivalence in patterning. The investigation of social factors which make some varieties better received or more widespread than others is a separate endeavor.

Role Theory
R. H. Turner

Role theory is often traced back to William Shakespeare's famous lines in *As You like It*:

> All the world's a stage,
> And all the men and women merely players;
> They have their exits and their entrances;
> And one man in his time plays many parts ...

Use of the term rests on two complementary commonsense observations. On the one hand, different people, when they find themselves in similar positions, behave and even think and feel similarly. On the other hand, the same individual, when placed in different positions, behaves, and often thinks and feels, differently. Furthermore, each role includes a cluster of expected behaviors—a *gestalt*—so that it is viewed as odd, inconsistent, or wrong when the physician sweeps up his own office, the parson frequents gambling parlors on his day off, or a child takes charge of family finances.

1. Definitions

A social role can be formally defined as: a comprehensive pattern for behavior and attitude; constituting a strategy for coping with a set of recurrent situations; socially identified, more or less clearly, as an entity; subject to being played recognizably by different individuals; supplying a major basis for identifying and placing people in society; and constituting a framework from which meanings are assigned to people's individual actions.

There are many useful ways to classify roles, but an initial distinction can be made among four types.

First are 'basic' roles such as gender and age roles. These are roles that individuals carry with them and are expected to play in almost every situation. They are partial determinants of eligibility to perform many specific roles and of how those more specific roles are to be played. 'Position' or status roles are more specific and are attached to formally designated positions in groups, organizations, and larger formalized social units. They include family roles, occupational roles, political office roles, and roles associated with participation in particular activities such as golfer, surfer, and stamp collector. 'Functional group' roles are behavior patterns that emerge informally in the course of sustained interaction in any group. For example, someone may play the role of leader without any formal group decision; others may play devil's advocate, mediator, or counselor. 'Value' roles are the roles that develop about strongly positively or negatively valued activity, such as the role of hero, saint, group exemplar, murderer, or thief.

Basic roles are embedded in culture so that thinking and acting in terms of them seem automatic, though aspects of them are often written into law for reinforcement. Position roles in social institutions such as the family are culturally defined, often with legal enforcement, while position roles in organizations are defined through some decision process accepted as legitimate for that organization. By contrast, both functional group roles and value roles are quite informal and based on images conveyed in the culture. In the course of sustained group interaction, individuals may wittingly or unwittingly

pattern their behavior so as to play a particular role with some consistency. Furthermore, people tend to categorize each other informally, and to interpret each other's behavior and behave toward each other according to the functional group roles. Once people are labeled in value terms, they are expected to continue to behave consistently with the label, so that heroes must live up to their prior achievements and criminals are constantly suspected of more evil doing.

Among the first social scientists to use the concept was the German sociologist, George Simmel. Brought to America, the concept was prominently embodied in four streams of scholarship. Robert E. Park and George Herbert Mead used it in laying the foundations for symbolic interactionism, a school of thought stressing human flexibility and creativeness, and using social interaction as the starting point for understanding larger social systems. Jacob Moreno used the concepts of role and role playing in his psychodrama and sociodrama as a way of making people aware of their own systems of interpersonal relationships, as an opening stage in psychotherapy. Kurt Lewin used the concept role to extend the insights of *Gestalt* psychology to a social psychology that stressed the structure and interrelationship of the social settings that link actors to one another. The most influential formulation of role was that of the anthropologist, Ralph Linton, who saw it as the key to refining the concept of culture so as to acknowledge that not everyone subjected to a common culture shared the same set of understandings.

2. Structural versus Interactional Role Theory

Linton's conception of roles as the sets of norms attached to particular statuses, culturally transmitted to the incumbents and interactants of given roles, accorded well with the behaviorist orientation of the early twentieth century. However, the overly mechanistic and consensual view of roles was challenged from two quarters. Robert Merton (1957) replaced impersonal cultural norms with 'expectations' conveyed by incumbents in the appropriate 'role set.' Like school superintendents who must accommodate their role enactment to the demands of teachers, students, parents, and school board members, role incumbents must deal with the divergent expectations produced by the diverse interests and points of view of a set of closely related other-roles. Because there are several alternate strategies for reconciling these diversities, there is room for considerable variability and innovation in role behavior.

Scholars in the symbolic interactionist tradition, incorporating the idea of role as a *gestalt*, posed a more fundamental challenge to structural versions of role theory. Interactionists argued that in most situations roles are vague and ill-defined, but individuals act as if they were clear-cut. The implicit assumption that roles are real and that people are enacting roles provides the framework within which individuals attempt to interpret each other's behavior and to shape roles for themselves. Interaction is a highly tentative process, crucially hinging on 'role taking'—imaginatively placing oneself in the position of other interactants so as to infer the roles they are playing and how they are playing them—and 'role making'—improvising a role for oneself that enables one to deal with others.

3. Role Differentiation

Whichever approach is taken, fundamental questions that arise are why and how various behaviors and attitudes become differentiated and grouped into roles, how actors are allocated to particular roles, and how roles are actually enacted. The principle that the division of labor becomes more complex, with tasks assigned to more and increasingly specialized roles, as the size of an organization or society increases and as the nature of the tasks becomes more complex, has been abundantly documented. Much less progress has been made, however, in understanding the principles that govern the way that tasks and attitudes are grouped and separated to form roles. Robert F. Bales demonstrated that artificial groups, meeting for several successive sessions, and assigned formal tasks to accomplish, often tended to develop two complementary leader roles. By concentrating on getting the job done, the task or instrumental leader created tensions in the group and had little time for dealing with members' interpersonal problems. If these tensions were not to disrupt group functioning, there had to be a social–emotional or expressive leader, who worked with members to relieve tensions and resolve interpersonal frictions. At one time this observation was proposed as the explanation for the nearly universal pattern of role differentiation in families, between husband as instrumental leader and wife as expressive leader. However, further research suggested that differentiation between instrumental and expressive leadership roles only evolved when group members lacked sufficient incentive for achieving group goals. On this and other grounds, use of Bales's observation to justify traditional family role patterns is discredited.

It has been proposed that the pattern of role differentiation is shaped by considerations of functionality, tenability, and representationality. Functionality refers to a division of labor that minimizes incompatibility of goals and means and conflicts of interest within roles, and accommodates to the differentiations of ability and disposition in the pools from which role incumbents are recruited. Representational differentiation separates and combines elements so as to accentuate value differences and similarities, and is often an overlay on functional

differentiation. A role is tenable when there is a tolerable balance between the rewards and costs of playing the role to the incumbents. What role construction is tenable depends upon the power that incumbents bring to the role and what configuration of behavior and attitude harmonizes with incumbents' self conceptions.

4. Role Allocation and Learning

The obverse of role differentiation is role allocation, the 'assignment' of individuals to particular roles. According to a substitutability principle, discordant or ineffectual role relationships often can be resolved alternatively by redifferentiating the roles or by reallocating individuals or categories of individuals among existing roles. When role theory is approached structurally, an important distinction is made between allocation by ascription or achievement. Ascription means that individuals are required to perform certain roles and not others by accident of birth or life stage, according to cultural or legal mandate. Achieved roles are acquired through the individual's own efforts or conduct, and include most roles except gender and age in modern societies.

The interactional approach sees role allocation as the everchanging product of negotiation in interpersonal and intergroup relationships. An important feature of this negotiation is a process of 'altercasting,' of attempting to manipulate situations so as to cast relevant others into those roles that enable individuals to seize the desired roles for themselves. Altercasting on an institutional scale is illustrated by the way in which blind people are coerced into playing a stereotypic blind role in order to receive services from social agencies and to have harmonious dealings with strangers and acquaintances (Scott 1969).

Whether ascribed or achieved, roles must be learned in order to be enacted. Thornton and Nardi (1975) have proposed that learning involves four stages. First is the anticipatory stage, in which one hears or reads about the role or observes a role model, but without directly experiencing the role. Understanding at this stage is superficial, often idealized and unrealistic. It is followed by a stage of formal learning in which the role is learned through attention to rules and regulations, official declarations, and cultural norms. Transition to this stage begins with entry into trade or professional school, apprenticeship, or directly into the role. It typically characterizes the early experience in the role when the individual is guided by formal rules and values. As one gains experience in a role one begins to learn that the role is not generally enacted strictly according to the formal rules, and one learns the role as it is more informally understood by experienced incumbents. In a final stage, the incumbent becomes

sufficiently secure in performing the role to begin to develop unique variations on the standard formal and customary informal role. The role is thus modified so as to fit uniquely the personality of the incumbent. Starting from a structural framework, this outline of stages concludes by stressing individual variability, consistent with an interactional approach.

The interactional approach calls attention to the fact that roles are normally learned in pairs or sets. Since role-playing depends upon role-taking significant other-roles, individuals must learn a good deal about these other-roles in order to master their own roles. While the learning of other-roles is usually limited to the anticipatory and formal stages and tends to be biased by the focal role's role-stand-point, individuals are sometimes able, in an emergency or other unusual situation, to assume and play the other-role when it has been abandoned. This process of 'role appropriation' has been observed when a child unexpectedly fills in for a temporarily incapacitated parent.

5. Role Enactment

Most social roles can only be enacted in interaction with relevant other-roles, and the nature of that interaction supplies the role's meaning. An important contribution of structural role theory has been to think of roles as consisting of rights and duties. The tenability of a role depends in large part on the balance between rights and duties, as it relates to the incumbents' relative power in the situation. A role is thought to be legitimate or fair if duties are balanced with rights. However, as interactionists point out, balance is largely in the eye of the beholder.

Seen interactionally, the balancing of rights and duties also means reciprocity, since one role's rights become another role's duties. At the very minimum, implementation of rights in one role requires that other-roles involve a duty not to prevent the focal role incumbent from exercising those rights. But the reciprocity is often much more active, as when the child's right to food and lodging implies an obligation for parents to provide those benefits, and as the employee's right to be paid for working implies the employer's duty to pay the worker. There is also another kind of reciprocity, in that what the focal role provides for the other should be in reasonable balance with what the other-role provides for the focal role. Thus 'exchange theory' and role theory come together at this point. It is a major proposition of role theory that discontent, inter-role friction, poor role performance, and disruptions of the role system result from incumbents' conviction that relationships are unfair because of an absence of reciprocity or balance in any of these respects. Again, interactio-nists caution that judgments, that

contributions are not equivalent and feelings of unfairness are often the consequence rather than the cause of disenchantment in role relationships.

Roles can be enacted with varying degrees of 'role adequacy,' and people tend to be evaluated within an organization and as persons on the basis of the adequacy with which they perform their roles. Besides personal skills and ability and disposition or motivation, role adequacy depends upon opportunity and resources. Role adequacy is also affected by 'intra-role conflict,' the presence of relatively incompatible expectations inherent in the role. Such incompatibility may be a consequence of the role set (as already discussed) or of an incompatible combination of tasks, as in the role of teacher who must be both educator and disciplinarian in a neighborhood of unruly children.

A further obstacle to adequate role performance can be 'inter-role conflict.' Role conflict refers to the experience of incompatible obligations from two or more of a person's roles. An example would be a minister of a church whose religious responsibility is to accept a very modest salary gratefully, but who, as a father, feels obligated to secure the best education for his children that money can buy. Role conflict can be a fairly moderate or quite intense experience, depending upon how deeply and equally committed the individual is to the roles involved and how irrevocable the consequences of a particular decision may be. For example, conflict between a business trip and a meeting of one's monthly bridge group is usually resolved with a minimum of stress by opting for the business trip because commitment to the occupational role is much stronger than commitment to the bridge group, and because consequences of missing the bridge group occasionally are not serious or irrevocable. By contrast, commitment to family roles such as parent, husband or wife, son or daughter, and brother or sister, is usually high. Nevertheless, in daily life, conflicts involving family roles are often resolved without great stress by temporarily setting aside family commitments because the effects are minor and temporary, and there are abundant opportunities to compensate. But when the life, safety, or health of a family member is at stake so that the consequences of failing to carry out one's responsibilities could be severe and irrevocable, the experience of role conflict will be intense unless the conflicting role is easily set aside.

Two quite different kinds of inter-role conflict are 'role value conflict' and 'role overload.' Value conflict is the more serious because it means that the more adequately the individual performs one role, the more he or she is dishonored in terms of the other role. But with the growing multiplicity of roles people play in modern societies, much more research has been devoted to role overload—the simple problem of not having enough time to perform all of one's responsibilities or of being unable to be in two places at the same time.

The term 'role strain' is sometimes used to describe the state of personal stress in the role-conflicted individual (Goode 1960), or the person who is unable to perform an allocated role adequately, according to his or her own standards, for any of the reasons reviewed. The ways in which people try to resolve role strain will be quite different, depending upon whether the cause of role strain is role conflict, inability to perform a task, or some other condition.

There are several ways to deal with role conflict. One way is 'role abandonment,' that is, opting for the responsibilities of one role and neglecting the responsibilities of the other. But abandonment can be permanent or temporary. The executive whose business trips conflict with bridge club meetings may resign from the bridge club, or the volunteer firefighter whose emergency duties too often conflict with family or occupational responsibilities may resign from the volunteer fire brigade. More often role abandonment is attempted as a one-time solution. But such one-time abandonment usually carries penalties or at least requires assurances of more serious commitment to the abandoned role in the future. For example, the father who is absent on his daughter's birthday because of a business trip will be expected to bring home a special gift and treat his daughter to some special entertainment as a 'peace offering' on his return.

When commitment to both roles is high, people often try to resolve role conflict either by contriving to perform both roles in some way, or by performing only part of their responsibilities to each role. For example, one may attempt to attend two conflicting meetings, leaving one early and getting to the other late. Or one might try to perform the responsibility that could be completed in less time first, before taking up the more time-consuming responsibility. Needless to say, this approach is often counterproductive, with the result that both roles are performed poorly, if at all. Still another resolution might be called double role abandonment. Early research showed that workers who were pressured by their employers to hold one opinion (employee role) and by their union officials to hold a different opinion (union member role) often lost interest in the issue entirely. Whatever resolution is chosen, the stress of severe role conflict can affect concentration, motivation, and attitude toward the roles in question.

While the association of role overload with stress in modern societies had long been accepted as proved, Samuel Sieber (1974) challenged the necessary connection between multiple roles and role stress. According to a principle of 'role accumulation,' benefits (rights) often accumulate faster than duties when one assumes additional roles. One can often combine the duties of two or more roles into a

single act, or use the benefits gained from one role as resources to help meet obligations of another role. This reasoning also led to questioning the common assumption that women who attempted to combine homemaker and professional roles suffered exceptional role strain. Several studies have now shown that levels of satisfaction are often higher among women who combine these two roles than among women who are involved in either homemaking or career exclusively. Specific outcomes are clearly affected by whether the single or dual role is a matter of personal choice or not and other variables not yet fully explored. Likewise, there is still much to be learned about the conditions that determine whether multiple roles will intensify role strain or lead to a rewarding role accumulation.

6. Organizational Roles

Most position roles are units in the division of labor by which some organization or institution functions. Consequently the content and arrangement of roles reflect the goals of the organization or institution. To insure that this is the case, organizations vest certain roles with the authority of 'legitimate role definers,' whose incumbents can change the organizational role structure and evaluate role performance in the organization. In order to minimize disruptive 'role ambiguities,' intrarole conflicts, and other role related threats to organizational functioning, highly formal descriptions of roles and their interrelationships are typically evolved. However, even in such rigidly formalized organizations as the military and police, incumbents of each organizational role develop their own shared informal role definitions. These informal roles incorporate practices which the role incumbents agree upon (informally) as the appropriate way to enact the role. They provide a role that is either more functional, more tenable, or more acceptable representationally than the formal role. They fill in remaining ambiguities in the formal role; for example, police must not use excessive force in making arrests, and police officers look to their peers to help define what is and is not acceptable force. They indicate which aspects of the role should contribute most to the incumbents' sense of self-fulfillment. They take account of compromises that must be made on pragmatic grounds, but which are unlikely to be admitted publicly in formal role descriptions.

Whether the informal role fosters the goals of the organization or undermines them depends upon the functionaries' degree of enthusiasm for organizational goals and their relationships toward organizational authorities. For example, the common practice of factory employees evolving their own standard of what constitutes a good day's work and informally sanctioning both under- and overachievers may be either a hostile slowdown of production or a means for keeping production at an optimum level consistent with maintaining worker well-being.

While role ambiguities and intrarole conflicts are generally considered to be damaging to organizational functioning, there is evidence to suggest that this is not always the case. For one thing, overly specific role statements may impair needed flexibility to deal with the unforseen. For another, some ambiguity and intrarole conflict can serve as a challenge, making role performance more interesting to the incumbent and encouraging innovations that may improve organizational functioning.

7. Roles in Society

The role that one plays and the adequacy with which it is played largely determine one's standing in an organization. For most roles there is little carryover of standing from one organization to another. But the implications of one's basic roles and value roles usually transcend any particular organizational setting. In addition, some highly valued position roles, such as one's profession, supply an important basis for standing in the society and not merely in the workplace.

Every society provides for certain situational or temporary roles that serve to exempt incumbents from normal responsibilities in most of their roles. Best known among these is the sick role. Talcott Parsons identified the sick role as a set of balanced rights and duties. When suitably certified as sufficiently ill—normally by a physician in modern societies but in other ways in other societies—role incumbents are temporarily relieved from many responsibilities in their occupational, family, community, and even friend roles and are entitled to be treated compassionately, provided that they are seriously cooperating with their physician and others in an effort to recover from the illness. The concept of how ill one must be and the criteria by which one is certified as ill, along with the kind of ministrations expected from family and friends and the range of responsibilities from which one is relieved vary greatly among different cultures and subcultures. Bereavement is another universally accepted exempting role. Other roles such as the drunken role and the stress role have their culturally specific configurations and are recognized as exempting roles under some circumstances in some cultures.

8. Role and Person

Because each individual plays different roles in different situations and at different life stages, and because people generally know each other by the roles they have an opportunity to see them play, the question for individuals and for those who know them is: who is the real person beneath the various role facades? Often people must play roles with which they would not want to be personally identified, and

63

even more often, they are concerned that the person revealed through a single role will be mistaken for their whole person. Under these circumstances, people often engage in 'role distancing' by feigning detachment from the roles they are playing or making light of their role performance.

For those behavioral scientists who believe there is a 'person' behind the various roles, it has been proposed that each individual's role repertoire is organized into a hierarchy of salience. The individual's self-conception is built around the most salient roles. The hierarchy is partly determined by cultural selection of 'master roles,' such as one's occupation in the USA and one's family roles in more traditional societies. But it also varies uniquely from individual to individual, based on one's personal socialization experience. The most salient roles are those to which the individual is most committed, and which the individual should perform most conscientiously. For the salient roles there is a process of role–person merger, indicated by a tendency to continue playing the role even in situations where it is not called for, to resist giving up the role even in exchange for a more advantageous role, and internalization of attitudes and beliefs appropriate to the role.

Role–person merger is caused in part by how others view one and is governed by an 'appearance' principle, that in the absence of contradictory cues people tend to accept each other as they appear to be; an 'effect' principle, that the greater the effect of one's particular role on others, the more they conceive one as the person revealed in that role; and a 'consistency' principle, that one is identified as a person on the basis of observed behavioral consistencies between situations. In spite of a 'consensus' principle, that we tend to see ourselves as others see us, individuals are also active in shaping their self-conceptions by emphasizing roles they play best and with greatest autonomy, and by identifying most strongly with roles in which they have invested the most effort, creativeness, and personal sacrifice.

Situational compartmentalization is the most important tactic by which people handle the variety of roles they play during a given span of time. However, the life course is characterized by a great many 'role transitions,' when people give up one role to take on another. These transitions, from only child to sibling, from single to married, to parenthood, to empty nest, from dependent child to self-supporting adult, through occupational promotions and demotions, to retirement, and many others, can take place smoothly or with much stress. Transitions to roles with less favorable privileges-to-obligations ratios, such as divorce, widowhood, unemployment, and often retirement are inherently stressful. In most other transitions the stress is attendant on mastering and being accepted in the new role, so the stress level reflects the degree of difference between the old and new role and, inversely, the social support from the role set in the new role. In some instances, the stress is less in acquiring a new role than in divesting oneself of the old role. Helen Ebaugh (1988) has examined the difficult experience of former nuns, formerly married persons, former convicts, and former alcoholics, who continue to be known as exnuns, exconvicts, divorcees, widows, and exalcoholics while attempting to assume new roles for themselves.

9. Role Change

Historic changes in gender roles, age roles, family roles, occupational roles, and others have been extensively documented and analyzed. Roles may divide like an amoeba, or coalesce; new roles may be created or old ones die out. Research, however, has mostly dealt with changes in the content of continuing roles. The impetus for change usually comes from broader cultural change in values connected with the focal role; social structural changes that modify demand for the services provided by the role, the availability of resources, or social support for performance of the role; or the size and personal qualifications of the pool of potential recruits to the role. These changes can work indirectly through modifying the role's supporting network or by inducing change in other-roles that are part of the role set, or directly by creating role–person misfit. If these conditions are not relieved by reallocation or by negotiating idiosyncratic roles for the misfits, they contribute to either dysfunctionality, untenability, or inappropriate representationality in the role.

Whether the impetus for change will lead to negotiated change in the role depends upon the costs of alternatives, structural autonomy of the role, unity and mobilization of role incumbents, mobilized client demand for services that the revised role would render, cultural credibility of the changed role pattern, and institutional support for change. If the role change would encroach on the rights and duties of other roles, active resistance and conflict can be expected, depending upon the costs of the change to the encroached and their unity and mobilization in resisting change, and on the scarcity and monopolizability of skills held by the focal role incumbents and the role's support structure. If enough of these conditions are sufficiently unfavorable for change, the outcome can be resignation. But if the balance is favorable, changes in the focal role and accommodating changes in the role set should follow.

10. Conclusion

Linguistically, social roles are among the most important nouns, naming the categories of persons who participate in language. From the perspective of the sociologists, all kinship terms (see *Kinship Terminology*) such as *mother, father*, or *cousin* name

roles. But the lexicon of roles is vast, including for example professional roles (*doctor, judge*), positions in sports (*quarterback, coach*) and nonfamily personal relationships (*leader, lover*). Indeed, to the sociologist any term that identifies a position in a social system can be understood as the name of a role.

One can speak of a grammar of roles, because every role exists in relation to other roles and each particular relationship entails expectations concerning how role incumbents will communicate. A leader is expected to speak authoritatively, while a follower is expected to cheer the leader's words. A judge pronounces judgments. A quarterback calls plays but listens to the advice of the coach. A doctor gives diagnoses and prescriptions. Lovers share intimate words that must not be uttered in public. As researchers pay increasing attention to the linguistic variations that exist within a speech community, they will be well advised to examine the effect of role playing upon language.

As we have seen, most roles can be assigned to one of four categories: basic roles, position or status roles, functional group roles, and value roles. Structuralist analysis emphasizes the consensual character of norms that define roles, while symbolic interactionists describe a more tentative process in which roles are taken and made. Sociologists of both schools have examined how behaviors and attitudes coalesce to form differentiated roles, and they also study how roles are allocated to individuals, learned by them, and enacted reciprocally with other roles. Of special interest to sociolinguistics, organizations vest certain roles with the authority to define and transform other roles. Throughout life, individuals play a variety of roles, more or less

adequately, managing role transitions, changes, and communications with others concerning the genuine person who wears all the masks. Language is the medium through which roles are created, and each role in turn shapes the language of the person who plays it.

Sapir–Whorf Hypothesis
O. Werner

1. Statement of the Hypothesis

The relationship between language and culture, or language and world view, has been noted at least since Wilhelm von Humboldt (1836). But discussion remained relatively dormant until the 'Golden Age of Native American Indian Linguistics' in the first half of the twentieth century.

Although everyone calls it the Sapir–Whorf hypothesis, its most persistent proponent was Whorf (Carroll 1956; see also *Whorf, Benjamin Lee*). And yet, perhaps surprisingly, the most popular formulation comes from Sapir (see *Sapir, Edward*).

1.1 Sapir's, or the Lexical, Version

Sapir never sought the interface between language and culture anywhere but in the lexicon. The quote below is used most commonly to characterize the Sapir–Whorf hypothesis:

> Human beings do not live in the objective world alone…but are very much at the mercy of the particular language which has become the medium of expression for their society. The worlds in which different societies live are distinct worlds, not merely the same world with different *labels* attached.
>
> (Sapir in Mandelbaum 1963: 162, emphasis added)

A similar statement stressing the classificatory or categorizing nature of language is expressed in even stronger terms by Whorf (though this quote is seldom used to characterize the hypothesis):

> We dissect nature along lines laid down by our native languages. The categories and types that we isolate from the world of phenomena we do not find there because they stare every observer in the face...
>
> (Whorf in Carroll 1956: 213)

Both quotes emphasize the words or lexical resources of a language. That is, both stress that while nature is continuous human beings cut nature into discrete categories and each culture does this cutting somewhat differently. People make up words or concepts in order to talk about their world or cultural universe.

This version of the Sapir–Whorf hypothesis is one of two alternatives. It is called the lexical version in this article. While one could ascribe the 'anomaly' that the hypothesis is usually characterized by the first, or Sapir's quote to some historical accident, there seem to exist deeper reasons that will soon become apparent.

1.2 Whorf's, or the Grammatical, Version

The view expressed by Whorf in the second quote (above) is relatively unusual. He searched for the interface between language and culture beyond the vocabulary (or the lexicon) and sought to discover the roots of cultural regularities in a language's grammar:

> ... the grammar of Hopi bore a relation to Hopi culture, and the grammar of European tongues to our own 'Western' or 'European' culture.
>
> (Whorf 1939: 73)

(The Hopi Indians live in villages in Arizona and speak a language of the Uto–Aztecan language family), and:

> By 'habitual thought' and 'thought world' I mean more than simply language, i.e., than the language patterns themselves.
>
> (Whorf in Carroll 1956: 147)

(following the usage of the times one can equate 'language patterns' with grammar), and again:

> ... the background linguistic system (in other words the grammar) of each language is not merely a reproducing instrument for voicing ideas but rather is itself the shaper of ideas, the program and guide for the individual's mental activity, for his analysis of impressions, for his synthesis of his mental stock in trade.
>
> (Whorf in Carroll 1956: 212)

Finally, in the statements in which Whorf gives the Sapir–Whorf hypothesis its alternate name, he again sees the relationship of language and culture in grammar.

> ... the 'linguistic relativity principle,' which means, in informal terms, that users of markedly different grammars are pointed in different evaluations of externally similar acts of observations, and hence are not equivalent as observers but must arrive at somewhat different views of the world.
>
> (Whorf in Carroll 1956: 221)

These quotes represent the second way of interpreting the Sapir–Whorf hypothesis—the grammatical version.

1.3 Discussion

The two versions of the Sapir–Whorf hypothesis or the 'linguistic relativity principle,' namely, the lexical version, espoused by Edward Sapir, and the grammatical, the predominant view of Benjamin Lee Whorf, have created considerable mischief in the profession. The reasons for the confusion lie in the different definitions of language used by anthropologists and linguists.

To anthropologists it was self-evident that the lexical resources of a language are part of that language. Therefore, the anthropological definition of language, at least implicitly, consists of phonology, grammar (syntax), *and* the lexicon.

The definition of language used by linguists explicitly excludes the lexicon. To this day linguists tend to give the lexicon short shrift. The science of linguistics considers only the structured parts of language amenable to analysis. One can easily detect pattern (i.e., structure) in phonology and in grammar (syntax). The lexicon was perceived as a 'collection of idiosyncratic features' (Gleason 1962), therefore not amenable to scientific analysis, and therefore outside of linguistics proper and, in the end, outside of what linguists considered to be language (perhaps best stated as 'language is what linguists do'). H. A. Gleason summarizes this view: 'lexicography is something that cannot be done but must be done.'

Several conferences about the hypothesis in the 1950s (Hoijer 1954, Hymes 1960, McQuown 1960) remained strangely inconclusive, largely because participating anthropologists and linguists operated with a basic misunderstanding about the nature of language. These conferences demonstrated vividly Kuhn's (1970) notion that discussions between members subscribing to two different scientific paradigms (views of the world) are always inconclusive. The irony of these discussions is that they are about language and world view, though Kuhn (1970) demonstrates that all world view disputes are hampered by the same sounding words used with different senses (e.g., 'language' as used by linguists versus anthropologists).

The Sapirean formulation of the hypothesis gained wide acceptance. The influence of grammar on world

view was difficult to demonstrate. Whorf's exotic interpretations of Hopi thought were often attributed to his imaginative native consultant (Carl F. Voegelin, personal communication). (Most of Voegelin's later work, with Florence M. Voegelin, dealt with the Hopi Indian language and culture, e.g., Voegelin and Voegelin 1957.)

Meanwhile the basic linguistic attitude changed from an orientation that 'every language must be described in its own terms' (the structuralist paradigm) to a preoccupation with language universals ushered in by Chomsky's transformational/generative revolution in linguistics. Suddenly all languages looked very similar.

Many more or less serious statements were made to this effect. Robert E. Lees is credited with asserting that 'all languages are dialects of English.' A few years later James McCawley 'corrected' Lee's assertion by declaring that 'all languages are dialects of Japanese.' McCawley's remark was prompted by the surface structure of Japanese which appeared to be very close to a universal, hypothetical deep structure valid for all languages.

The interdependence of a culture and the lexicon that speakers associate with that culture to talk about their experiences seems almost obvious—especially to anthropologists. The validity of the hypothesis was, of course, of much greater interest to anthropologists than to linguists and found, concurrent with the Chomskyan revolution but independent of it, expression in the New Ethnography (Sect. 3).

In 1970 Oswald Werner demonstrated that the contribution of grammar to world view can only take place through grammatical categories. However, grammatical categories are, in the prevailing theories of linguistics, inherently part of the lexicon—specifically of lexical entries. In transformationalist theories of language these lexical entries are in the semantic component of the grammar of specific languages. Each entry of the form (C, P) has a conceptual part C—a representation of the 'meaning'—and a phonological part P—representing directions for pronouncing the entry. Therefore, the 'linguistic relativity principle' becomes an investigation of the relationship between a culture and its associated lexicon—including grammatical categories.

It may be useful to recapitulate briefly Werner's argument. His demonstration starts with the Chomskyan assumption that the parts of a grammar are known and can be represented by the formula (1):

$$G(\#, \frown, \rightarrow, S, V_{nt}, V_t) \qquad (1)$$

where the # symbol represents the boundary conditions of a sentence (or utterance). This is the silence (absence of speech) that precedes and follows every sentence. The $\frown$ symbol stands for the operation of concatenation. The rewrite symbol $\rightarrow$ (right arrow) stands for the rewrite operation that specifies structure, for example, the formula (2):

$$S \rightarrow NP \frown VP \qquad (2)$$

(read: 'rewrite sentence as consisting of a noun phrase followed by a verb phrase') specifies the structure of S, the sentence, that consists of a noun phrase followed by a verb phrase. Thus, S in (1) stands for sentence, V_{nt} for the nonterminal vocabulary of the grammar, such as NP and VP in (2), and V_t for the terminal vocabulary. These lowest level units of a grammar or grammatical categories have no further structure (no rewrite rules can be applied and therefore these symbols never appear on the left side of any rewrite rules). In the process of sentence generation or production, actual lexical entries replace terminal vocabulary items in each language in question. (For details on the rules governing lexical insertion into terminal grammatical categories see the publications of Noam Chomsky.) Typical terminal categories are 'mass noun,' 'count noun,' 'performative verb,' 'manner adverbial,' 'definite article,' etc.

Obviously, #, $\frown$, and $\rightarrow$ are part of the formalism of all grammars, hence language universals, and cannot therefore contribute to meaning and world view.

The high level nonterminal vocabulary V_{nt} are assumed by linguists to be also universal, that is, they occur in every language and cannot therefore influence language specific world views. Languages such as Nootka (one of a large number of languages spoken on the northwest coast of the USA) which consists almost entirely of verbs, and Sierra Miwok (one of a large number of languages spoken in the state of California), which consists almost entirely of nouns, can be made to conform naturally to the structure of noun phrases and verb phrases. In Nootka nouns are formed by nominalizing verbs (English analog: to walk—to take a walk) and in Sierra Miwok verbs are formed by verbalizing nouns (English analog: table—to table, e.g., a motion).

The above argument leaves only the low level nonterminal (V_{nt}) and the terminal (V_t)—the lowest level of grammatical categories of a given language—as potential contributors to language specific aspects of world view.

If M. A. K. Halliday's principle of 'delicacy' is now added, that states that when the limit of linguistic analysis (the ultimate delicacy) is reached, then every lexical item in every language represents its very own unique grammatical category.

The parts of grammar that could contribute to world view are therefore the low level nonterminal and the terminal grammatical categories. But since these are part of the lexicon, in any language, the interaction of language and culture must be seen as firmly rooted in the lexicon.

Ultimately, therefore, the Sapirean definitions and the definition of the hypothesis in Whorf's first quote of this article prevail. In the other, the Whorfian formulation, the terms 'grammar,' or 'pattern,' should be consistently read as standing for 'low level grammatical categories,' or 'language specific grammatical categories.'

2. The Contribution of Grammatical and Lexical Categories

Before examining the issue of how these language specific categories contribute to world view, two additional notions require discussion: the strong version of the Sapir–Whorf hypothesis, according to which language *determines* thought, and the weak version, which asserts that language has a tendency to influence thought. Whorf is often viewed as representing the strong version. However, a review of his quotes (for example, in Sect. 1.2) reveals that he always qualifies his assertions.

While Whorf does say that speakers of different languages 'must arrive' at different interpretations of the world, these interpretations are not totally different only 'somewhat different' (Whorf in Carroll 1956: 221). Hopi grammar does not determine Hopi culture only 'bore a relation to [it]' (Whorf 1939: 73). And the 'background linguistic system' is not a determiner of ideas but merely a 'shaper of ideas.' He talks about 'habitual thought' rather than thought fully determined by the language of the speakers. It is thus difficult to find representatives of the strong version of the hypothesis.

All other points of view, including Whorf's, represent relatively stronger or relatively weaker versions of the weak version of the cultural relativity principle. The Sapir–Whorf hypothesis can therefore be paraphrased as follows:

> The categorial system of every language, including lower level grammatical and all lexical categories, points its speakers toward somewhat different evaluations of externally similar observations. Hence speakers of different languages have somewhat different views of the world, somewhat different habitual thought, and consequently their language and cultural knowledge are in a somewhat different relationship to each other. They don't live in the same world with different labels attached but in somewhat different worlds. The more dissimilar two languages are, in their lexicon—that is, in conceptual and grammatical categories—the greater their tendency to embody different world views.

Finally, Whorf's search for traces of world view in grammar, or in grammatical categories, is not without merit considering that different parts of language tend to change at different rates. Thus lexical items referring to objects change fastest as technology and customs change. For example, in Anglo–American culture new words like 'jeep,' 'radar,' 'laser,' 'napalm,' 'frozen yogurt,' 'yuppie,' and many others are quickly adopted into everyday use.

Verbs change more slowly. For example, until 1957 only planets, comets, and meteorites could orbit. Since Sputnik, the Soviet Union's first artificial satellite, an assortment of objects propelled into space are in orbit. A few years ago a telescope could not be thought of as orbiting. However, with the Hubble Deep Space Telescope in orbit, the range of the verb has been extended even to human beings. For example almost everyone understands the sentence *The astronauts are orbiting the earth*. There are other verbs introduced or extended by the rapid changes in Anglo–American culture. For example, *I word processed all morning*; *This program is good at error trapping*, etc. Not too surprisingly, new verbs are harder to think of than new nouns.

Still rarer are examples of changes in low level grammatical categories. These aspects of language change slowest and have therefore a much more lasting influence on 'habitual thought.'

In the following sections the amended definition of the Sapir–Whorf hypothesis (above) is used to explain a number of anomalies in the relationship between language and culture.

2.1 The Role of Different Symbol Systems

This amended definition still contains some mystification, for example, the dilemma of how it is that different categorial systems, that is, different languages, lead to somewhat different world views.

The insight that the choice of a symbol system is crucial to the solution of a mathematical problem is attributed to the Hungarian mathematician George Polya. A solution may be easy, difficult, or impossible depending on how a problem solver symbolizes the problem. Though mathematical problems are hardly identical with human problems for which language may provide a symbolization, mathematical problems display many similarities to such problems. Language provides human beings with categories of thought (see Lucy and Shweder 1979, below); these may or may not facilitate thinking in a given cultural domain.

It is clear from the Ethnoscience movement of the 1960s and 70s that speakers of different languages often do classify things very differently. For example, the Navajo Indians classify the plant world as in Fig. 1.

It is clear from Fig. 1 that Navajos use different criteria for classifying plants than do speakers of English. Strangely, in Navajo—with about 500 named plants—no further subdivisions of even the largest class of flexible plants seem to exist.

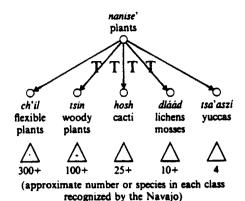
However, alternate classifications do exist. One Navajo medicine man classified all plants according to their use. The surprise was a subclass of dangerous


Figure 1. Navajo classification of plants. The T's symbolize the taxonomic relationship, e.g., *hosh nanise' át'é*, or 'A cactus is a (kind of) plant.'

plants that were poisonous. However an even greater surprise was that each dangerous plant has an antidote plant that can undo the effect of the poison.

One more unusual example showing that a language can facilitate talk (and solutions?) on some topics: the Navajo language has a rich vocabulary for describing the 'behavior' of lines. I list half a dozen examples from a growing corpus of about 100:

dzigai	a white line running off into distance (infinity)
adziisgai	a group of parallel white lines running off into distance
hadziisgai	a white line running vertically upward from the bottom to the top of an object
ahééhesgai	more than two white lines form concentric circles
alch'inidzígai	two white lines coming together to a point
álnánágah	a white line zigzagging back and forth

The ease with which Navajos talk about the behavior of white and other colored lines is amazing. This facility with 'geometry' is perhaps explainable by Navajo names or descriptions of features of the landscape that rarely utilize similarities to everyday objects (e.g., Hat Rock). Instead Navajos use geometrical description of verticals, horizontals, lines, and points. For example, a rock formation near Tuba City, Arizona, called by Navajos *Tsé Áhé'ii'áhá*, 'two rocks standing vertically parallel in a reciprocal relationship to each other' was named by English speakers 'Elephant's Feet.'

2.2 Language and Culture Do Not Covary

The *perfect* correlation of different cultures speaking different languages was an artifact of the biases of early cultural anthropology. In the formative years of the profession each ethnographer selected his or her own tribe with a distinct language. Nevertheless, anomalies to language/culture homogeneity were soon noted.

Three small tribes in Northern California represent the paradigm case. The Yurok, Karok, and Hupa Indians (the Yurok language is distantly related to the Algonquian, Karok to the Siouxan, and Hupa to the Na-Dene (Athabascan) language family) in the Klamath and Trinity river valleys near the California–Oregon border speak three different languages belonging to three different language families, yet their cultures are almost identical.

The linguistic record is incomplete, but there is evidence that many lexical categories (and possibly grammatical categories) were converging in the three languages. For example, all three use the phrase 'fish eater' for naming the sea otter.

There is growing evidence that extensive language and cultural leveling appears in areas where speakers of very different languages live in close proximity and in intimate contact with each other. For example, on the border of the Indo-European and Dravidian languages of India there are communities where vocabulary and grammar of the two languages (Marathi, Indo-European and Kannada, Dravidian) converge to such a high degree that people do seem to live in an almost identical world with different labels attached (Gumperz 1971).

In other words, very different languages can, over time, under the influence of their converging cultures, level many of their differences, while similar languages may diverge over time if their cultures are developing in different directions.

Examples of the latter case are the Apachean languages of the southwest USA. The Navajo Indian language, in the Apachean group, accommodates a culture that incorporates many Puebloan traits into its world view. None of the Apachean-speaking tribes live in villages. The Puebloan villagers have relatively homogeneous cultures but speak a diversity of languages. The other Apacheans did not assimilate Puebloan elements into their culture. Navajo and the other Apachean languages do remain similar, but the Navajos use extensive specialized vocabularies (and folk theories) appropriate to their world view that is alien to the other Apachens.

2.3 Language Mixing

Bilinguals when in each other's company tend to mix languages. The reasons seem obvious. There are many things that can be said better, more efficiently, in an aesthetically more pleasing manner, in one language than in another. Language purity is usually maintained only in the presence of (especially) high status monolinguals who would consider mixing the discourse with an unknown language offensive.

Language mixing, a universal occurrence when bilinguals converse, provides a good indicator of

69

the utility of the idioms or technical vocabulary of one language over another. That is, different languages offer different (more or less elegant?) solutions to speech about the same or similar 'cultural things.'

2.4 Language Acquisition

Since all definitions of culture stress that culture includes all things '... acquired [learned] by man as a member of society' (Tylor 1958), any language learned by children belongs therefore within culture. This fact underlies the formulation of the relationship as 'language *in* culture.'

However, many scholars became concerned that language is not just 'in culture' or 'part of culture,' but is also the major vehicle for the acquisition of culture. The confusion of culture with its chief vehicle of transmission proved troublesome, particularly since language is held responsible for the cumulativeness of culture. That is, language makes possible not only the transmission of culture, but also the increase of culture from generation to generation. This cumulativeness through language is the major mechanism of cultural evolution.

The solution, while 'obvious' in light of the developments of cognitive anthropology (Ethnoscience and New Ethnography are near synonyms) was nevertheless never clearly formulated (see *Ethnography of Speaking*).

Only one additional assumption need be made: the acquisition of language by a child has a natural history and in the course of this development language changes its function. At first the child learns its native language 'as a member of society' and therefore following the standard definitions of culture, language is part of culture (see *Child Language: An Overview*).

However, there is more to it. Language acquisition specialists agree that language learning is complete by the age of 4–6 years. Formal education, the institutionalized commencement of the acquisition of culture through language, begins after the child fully masters its native language. This happens universally at the age of 5 or 6 years. The child has now completed learning those aspects of culture that do not require language and begins to learn the accumulated wisdom and technology of the social group in which it is growing up, and that is encoded in language. Through language the child learns the verbalizable aspects of his or her culture. The function of language has shifted, now culture is in language, or it is acquired through language.

3. Cognitive Anthropology and the Sapir–Whorf Hypothesis

The New Ethnography or Ethnoscience entered anthropology with two papers published in *Language* by Floyd Lounsbury (1956) and his student Ward Goodenough (1956). The topic was a componential analysis of the Pawnee (which belongs to the Cadoan language family and was spoken in the southern Great Plains) and the Trukese (Austronesian-speaking Micronesians) kinship systems.

The point of componential analysis, in the context of the Sapir–Whorf hypothesis, is that kinship terminology (see *Kinship Terminology*) or the kinship lexicon of every language/culture combination views the same kinship space, but tends to subdivide it differently. The examples of kinship terminologies confirm the 'linguistic relativity principle.' Speakers of languages in different cultures experience the same 'objective reality' but assign different terminology to it. The speakers of different languages lexicalize (set to words) the universal kinship space very differently.

For example, the Yankee kinship system used by English-speaking North Americans merges all cousins: most Americans no longer fully understand the terminology that classifies cousins by degree (first, second, ... cousin) based on the distance from a common ancestor (first cousin = two generations, i.e., shared grandparents, etc.) and by generational distance (once, twice, ... removed).

For example, Tagalog, the main language of the Philippines, makes no distinction between grandparents and grandparents' brothers and sisters. Crow and Omaha, both Siouxan languages spoken in the Great Plains, merge some of the terms for cousins with certain aunts or uncles. Since the Crow reckon descent through the maternal line (they are matrilineal) and the Omaha through the parental line (they are patrilineal) the two systems are mirror images of each other. Navajo and Hungarian, a Finno–Ugric language of central Europe, on the other hand, make a careful distinction between the relative age of brothers and sisters. The list of culturally prescribed differences in kinship terminologies is virtually endless.

Componential analysis was soon followed by the discovery of folk taxonomies. Folk classifications had been noted before (e.g., Mauss 1964) but this was the first time that anthropologists/ethnographers collected folk taxonomies systematically. The seminal monograph was Conklin's *Hanuno'o Agriculture* (1954; the Hanuno's are Austronesian speakers living on the island of Mindanao in the Philippines). A flurry of activity followed taxonomizing everything from ethno-anatomies to folk zoologies. Werner et al. (1983) even presented the taxonomic aspects of the entire traditional Navajo universe.

In this lively debate the Sapir–Whorf hypothesis was mentioned only rarely and often outside the context of the New Ethnography. The participants in this ferment tacitly assumed that componential analysis and folk taxonomies clearly demonstrate the weak lexical version of the hypothesis.

Out of these developments arose cognitive anthropology that took as its goal the investigation of human cognition, especially cultural knowledge. It soon developed two branches. One is ethnoscience ethnography, which tacitly assumes the validity of the weak lexical form of linguistic relativity but does not elaborate this link to the past. The more pressing task is seen as the perfection and systematization of ethnography.

The second branch moved closer to cognitive psychology and by that route to cognitive science. Berlin and Kay (1969) soon emerged as the leaders in this field with their work on color terminology. That different language/culture groups have different color terminologies was considered in the debates of the 1950s and early 1960s the prime example of the lexical version of the Sapir–Whorf hypothesis. Obviously, the color spectrum is a continuum of colors from red to purple, but human beings in different parts of the world partition this continuum differently.

Berlin and Kay's first important discovery was that the color spectrum is not a good example for the hypothesis. '[C]olor categorization is not random and the foci of basic color terms are similar in all languages' (Berlin and Kay 1969: 10) and '... the eleven (see Fig. 2.) basic color categories are pan-human perceptual universals' (Berlin and Kay 1969: 109).

However, Berlin and Kay (1969: 160 n.2) stress that their work should not be confused with a thorough study of the ethnographic ramifications of color terminology. That is, '... to appreciate the full cultural significance of color words it is necessary to appreciate the full range of meanings, both referential and connotative...' or the lexical/semantic fields in which individual color terms are embedded.

Their second discovery was that color terminology evolves in a very lawful sequence. Although their formula has been 'fine tuned' following new cross-cultural data, it can be represented as shown in Fig. 2. (their original formulation, 1969: 4).

Lucy and Shweder (1979) revived the controversy by showing in several well-designed experiments that color memory is highly sensitive to the lexical resources of a language and culture. They conclude that the universality of color categories is overstated by Berlin and Kay and that the weak Sapir–Whorfian lexical formulation corresponds more closely to the facts.

Willet Kempton extended the methodology of cognitive anthropology to the shapes of objects, thus exploring the boundary between categories. Cecil Brown applied the evolutionary idea in Fig. 2. to other aspects of human vocabularies, especially botanical and zoological terminologies.

Ethnographers soon expanded their view beyond componential analysis after it was shown by a number of anthropologists and linguists that components are also lexical items and hence most often language specific rather than universal. John Lyons's critique of componential analysis as a universal theory for cultural knowledge (and semantics) is devastating. Nevertheless, componential analysis remains a superb tool for understanding exotic kinship terminologies.

In 1970 Casagrande and Hale, who had collected a large number of folk definitions in Papago (an Uto–Aztecan language of southern Arizona) published 13 lexical/semantic relations. They failed to find examples of a postulated 14th, the part/whole relation. A close analysis of their data shows that the part/whole relation did appear in its inverse form: that is, instead of 'A is a part of B' they found and classified as a spatial relation the inverse 'B has an A.'

Casagrande and Hale's work was seminal for a number of researchers (see the summary in Evens et al. 1980). Through these scholars their work was linked to the cognitive sciences. However, this link did not develop into strong ties.

The major insight of field theory can again be framed in terms of the linguistic relativity principle: the weak lexical version is accepted as self-evident. The lexical/semantic fields of the languages used in different cultural contexts look very different. However, there is unity because the lexical/semantic fields are held together by *universal* lexical/semantic relations.

Unfortunately there is no agreement on the basic set of lexical/semantic relations which range from Werner's (Werner and Schoepfle 1987) two to the over 50 lexical relations of Apresyian et al. (1970). Werner's two relations are 'taxanomy' and 'modification' plus several derived complex relations, a relation for sequential phenomena, and logical relations, including modal logic. Apresyian et al.'s relations are derived from practical lexicography or the construction of more systematic dictionaries. For example, their relation EQUIP is the relation in 'ship' EQUIP 'crew' ('A crew operates a ship'). The folk taxonomic model can be applied to whole cultures. Closely related encyclopedic works display the lexical

Figure 2. The cultural evolution of color terminology. If a language has the term 'red,' then it also has 'black' and 'white'; if a language has the term 'green' and 'yellow,' then it also has 'red,' 'white,' and 'black,' etc. The more technologically developed a given culture, the more of the 11 basic color terms are in use. (In the third box either order of [green < yellow] or [yellow < green] is possible.)

and cultural knowledge dimensions of a culture. That is, a background document fully exploring the lexical resources of a language represents an important aspect of the culture as a whole.

Ethnography is seen by many scholars as translation *par excellence*. Ethnographic translation fundamentally encourages translator's notes (definitions), which explain cultural ramifications of lexical items (or phrases) in native texts. Therefore, a carefully documented encyclopedic lexicon may represent an extensive set of translator's notes prepared in advance of the analysis of any future ethnographic texts.

An extension of these ideas is the recent focus on cultural schemata (Casson 1983). Schemata, recast into the lexical version of the Sapir–Whorf hypothesis, are folk theories often labeled by words (especially verbs) or phrases that usually require complex (e.g., up to monograph length and beyond) explanations or folk definitions.

4. Summary and Conclusions

The choice of the symbol system (e.g., language) affects the ease or difficulty with which one can talk about particular domains of cultural reality and solve problems in them. Thus the lexicon of language does provide a loosely laced straitjacket for thinking because it limits individuals to customary categories of thought. Only in this sense does it constrain thought.

At the same time language allows the inventive human mind to create alternative categorizations for solving new problems. This history of science and the rich diversity of thousands of human languages and cultures attests to the inventiveness of the human spirit.

True, the combinatorial possibilities in human language are enormous. Thus the very use of language results in a drift of meanings and with it inadvertent changes in world view. This process is analogous to genetic drift. But in addition there are analogues and historical examples of meaning mutations: conceptual revolutions and conversions.

However, these escapes from the mold of one's habitual language patterns are never easy— '...anomaly is recognized only with difficulty' (Kuhn 1970). It usually takes genius to show the rest of humanity how to see the world in a new light, that is in new categories. In such conversion experiences the language is affected 'to the core' (Kuhn 1970)— specifically, most grammatical categories remain the same but geniuses revamp lexical categories in ways that facilitate new thought which the rest of humanity may in time follow.

5. Epilogue

In a volume of edited articles, the editors, Gumperz and Levinson (1996) propose a new approach to linguistic relativity. They and their authors assume that indexicality, a broader concept than deixis, is highly culture specific and use it as their point of departure. Most simply, indexical terms are extra-linguistic references such as 'here,' 'there,' 'this,' etc. that depend on the cultural context of the utterance for their proper interpretation. Interestingly, all of the authors of this volume seem to assume that the notion of 'context' is not problematic nor is it theoretical. With a few exceptions (e.g., Hanks) context is assumed to be somehow intrinsically given and not linked to folk-theoretical knowledge of the physical, spatial, temporal, and ultimately the cultural world of the speaker. Unfortunately, this notion of 'context of situation' as extralinguistic goes back at least to Malinowski (1923) (see *Malinowski, Bronislaw Kaspar*).

Context must be viewed as a theoretical concept that has to be matched by experience when language is applied to that experience. This is not unlike the matching of attributes to events in the 'real' world. For example, the attribute 'green' must match the 'real' world grass when we talk about grass, or the shape and stripes of a tiger have to match a 'real' tiger or a picture of it, if that is what we are talking about. In this sense what we generally designate as context is like a generalized attribute; one that is not attached to individual words, but adheres to parts of or an entire discourse. Context, or contextual attributes, must be viewed as nested: larger ones within more local ones. For example, within scientific discourse, there are many further specifications of subcontext attributes possible.

However, sudden shifts in context, that is, in discourse attributes, are not uncommon in every day speech. Human beings are very good at detecting such shifts almost instantly. These shifts are associated with partitions of a person's cultural knowledge. That is, there does not exist any situation (or context) that requires all of human knowledge to be engaged simultaneously. This accounts for the fact that while language is in general highly ambiguous, humans are rarely aware of the ambiguity of their speech. Recognition of such a set of 'contextual attributes' allows only a very limited set of interpretations; very often it constrains interpretation to just one plausible understanding.

An added advantage of the contextual partition of cultural knowledge is that the 'same' words, phrases, or sentences can be used with different interpretations in such contexts that are analogous to partition of memory. This makes language adaptable to a much wider range of experience than would be possible if meanings were rigidly context (knowledge partition) independent. It is also clear that memory partitions (i.e., contexts) are highly culture specific.

A situation (or a hierarchy of the situation's attributes) either match our previous knowledge and expectations or they do not. Without the theoretical notion of such matches context mistakes would be impossible. Yet context mistakes are

common and may be viewed as situations in which the expectations of a speaker do not match the assumptions of his or her potential audience. For example, someone shouting within a library, or a church, or a lecturer speaking about a serious topic becoming unintentionally funny.

If we define culture as cultural knowledge (encompassing everything a member of a culture needs to know to function appropriately), then we can equate cultural situations with what we often call 'context.' Since cultural knowledge accrues to any human group over time, so too does context sensitivity adapt to the expectations of the group. Because all of us as human beings belong to several human groups (perhaps $7 + 2$ groups based on the limitations of our short term memory), we are all multicultural. Hence as the group-we-are-in changes so does the contexts that determines the framing for indexical expressions. We tend to be very sensitive to these changes. Thus indexicality, by its very nature, is culture bound and indexical expressions tend to be highly culture specific. That is, of course, precisely what the authors in the Gumperz and Levinson (1996) volume advocate while failing to consider the notion of 'context' as problematic and theoretically interesting.

Saussurean Tradition and Sociolinguistics

J. E. Joseph

The Swiss linguist Ferdinand de Saussure (1857–1913) established his reputation at an early age, with his 1878 monograph *Mémoire sur le systéme primitif des voyelles dans les langues indo–européennes*

('the original vowel system of the Indo–European languages'). *The Mémoire* posited the existence of two Proto-Indo–European 'sonant coefficients' which appeared in no attested forms of the daughter languages, but could account for certain vowel developments which had previously appeared irregular. Fifty years later an *H* with exactly the distribution of Saussure's sonant coefficients was discovered in Hittite, confirming his hypothesis. After his 1881 doctoral thesis on the absolute genitive in Sanskrit, Saussure published no more books, only articles on specific topics in historical linguistics.

But in 1907, 1908–1909, and 1910–1911, he gave at the University of Geneva three courses in general linguistics, a topic on which he never published anything. Soon after his death in 1913, his colleagues Charles Bally (1865–1947) and Albert Sechehaye (1870–1946), appreciating the extraordinary nature of the courses Saussure had given, began gathering what manuscript notes they could find, together with the careful and detailed notebooks of students who had taken one or more of the three courses, especially Albert Riedlinger (1883–1978). From these they fashioned the *Cours de linguistique générale*, published at Lausanne and Paris in 1916. It would become one of the most influential books of the twentieth century, not just for linguistics, but for virtually every realm of intellectual endeavor.

In order to trace the Saussurean tradition in twentieth-century linguistics, this article considers nine key elements of Saussure's view of language. For each a summary is given of the condition prior to Saussure, of Saussure's own view, and of how his view has shaped linguistic inquiry in the years since the publication of the *Cours*.

1. The Establishment of Synchronic Linguistics

At the time of Saussure's lectures, the study of language had been dominated for over 30 years by (a) historical work on the language of written texts (work which had only gradually come to be distinguished from 'philology,' inquiry aimed not at the language but at better understanding of the text itself); (b) dialectological work based on field investigation of local dialects; (c) phonetics, which demanded increasingly minute observation in strong adherence to the positivistic spirit; and (d) psychology, the principal domain of a global perspective on language, dominated by the ideas of Wilhelm von Humboldt (1767–1835) and his followers, notably Heymann Steinthal (1823–1899) and Wilhelm Wundt (1832–1920).

A fifth approach existed—the study of language as a general phenomenon independent of historical or psychological considerations—but it had made little progress since the death of its principal exponent, the American scholar William Dwight Whitney

(1827–1894). Furthermore, the publication of a major study of language in 1900 by the Leipzig psychologist Wundt appeared to signal that the new century would give the 'general' study of language over fully to that discipline.

Saussure's problem was to delineate a study of language that would be neither historical nor ahistorical, neither psychological nor apsychological; yet more systematic than Whitneyan general linguistics, so as to be at least the equal in intellectual and methodological rigor to the historical, psychological, and phonetic approaches. His solution was to make a strong distinction between the study of language as a static system, which he called 'synchronic' linguistics, and the study of language change, which he called 'diachronic' linguistics (or, until 1908, 'evolutive'). Saussure's rejection of the traditional term 'historical' seems to have been based in part on a disdain for the reliance it suggested upon extralinguistic factors and written texts, and in part on a desire for terminological symmetry with 'synchronic.' Synchronic linguistics would henceforth designate the study of language systems in and of themselves, divorced from external considerations of a historical or psychological sort, or any factor having to do with actual speech production.

This is the single most sweeping of Saussurean traditions for insofar as twentieth-century linguists have focused their efforts neither on simple description of languages, nor on their evolution, nor on their connection to 'national psychology,' they have realized Saussure's program of synchronic linguistics. Furthermore, historical linguistics has largely become the diachronic enterprise envisioned by Saussure (though the term 'historical' continues in general usage), and even the purely 'descriptive' approaches have been profoundly marked by the Saussurean concept of language as a system where *tout se tient* ('everything holds together'), a phrase often associated with Saussure, though there is no record of his using it in his Geneva lectures. It may be that its first use was in a lecture delivered by Antoine Meillet in 1906 (see Meillet 1921: 16).

In establishing synchronic linguistics, Saussure was not engaging in an exercise of scholarly exactitude, but serving notice upon psychologists and others that the general study of language should fall to persons with historically based training in specific languages and language families, rather than to experts in the functioning of the mind. Many of Saussure's statements about language can best be understood in conjunction with this need for establishing the autonomy of linguistic inquiry vis-à-vis adjoining fields.

2. The Primacy of Spoken Language

The idea that speech is the original and primal form of language, and writing a secondary imitation of

speech, runs counter to the general popular accordance of greater prestige to writing. Yet the primacy of spoken over written language became embedded in linguistics in the early nineteenth century, doubtless in connection with the Romantic belief that folk traditions embodied the national spirit more deeply than urban practices like writing, which were more subject to external influences. The trend continued over the course of the nineteenth century as linguistics moved away from philology and became increasingly concerned with the gathering of spoken forms from living dialects. By the turn of the twentieth century few linguists would have disputed that the best source for determining the original form of anything in any language was to reconstruct it from its living descendant dialects, and not from written records surviving from intermediate stages.

Saussure formalized the marginalization of written language as well as anyone, and if its survival is often viewed as a Saussurean tradition, it is because he has borne the brunt of the 1967 attack on this marginalization by Jacques Derrida (1930–). For Saussure, writing is not language, but a separate entity whose only 'mission' is to represent real (spoken) language. The 'danger' of writing is that it creates the illusion of being more real and more stable than speech, and therefore gains ascendancy over speech in the popular mind. Derrida demonstrated the irrationality and internal inconsistency of this extreme phonocentrism; in his deconstructionist wordplay, all language is a kind of 'writing' (in a sense that is unique to Derrida).

But so deeply ingrained is this tradition in twentieth-century linguistics that few linguists saw the need to respond to Derrida, whose critique was summarily dismissed. Well over 10 years passed before linguists began to admit that the marginalization of writing had been carried to an irrational extreme; and despite some tentative steps toward a linguistics of writing in various quarters, this tradition of privileging spoken language—shared though not founded by Saussure—is in no danger of passing away.

3. The Object of Linguistics: *Langue* versus *Parole*

The role of the human will in language production has constituted a problem for linguistic thought at least since Plato's *Cratylus*: humans are constrained by the conventions of language, yet it is through language that will and individuality are shaped and realized. Since modern science is predicated upon the elimination of the will from any object of inquiry, human desire, action, and creation came to be excluded from the 'scientific' study of language. This has necessitated a considerable abstraction of language away from its role in human affairs, treating it as if it existed independently of speakers and speech acts. But here two problems arose: (a) the metaphor

of language as organism (which qua metaphor had been fruitfully employed by early nineteenth-century linguists) became extremely attractive as a way of talking about language independently of speakers, and as Michel Bréal (1832–1915) complained in the introduction to his *Essai de sémantique* (1897), the metaphor was taken literally by many people, giving rise to gross misunderstandings; (b) Wundt's *Völkerpsychologie* ('national psychology') seemed to offer a more sophisticated way of dealing with linguistic phenomena: it eliminated the metaphysical abstraction of 'language,' but replaced it with still less satisfactory explanations that revolved around the 'spirit of peoples,' were untestable, and could not sustain any approach to language that was detailed or systematic.

Saussure's contribution was to dissect the total phenomenon of language (*language*) into (a) actual speech production (*parole*), including the role of the individual will, and (b) the socially shared system of signs (*langue*) that makes production and comprehension possible. Although he spoke of a linguistics of *parole* that would cover the phonetic side of language and the products of individual will, Saussure made it clear that the linguistics of *langue* is the essential, real linguistics. *Langue* is beyond the direct reach of the individual will. Saussure's formulation is both a defense and a refinement of the procedures of traditional grammar and historical linguistics, yet at the same time it stakes out an autonomous realm for general linguistic inquiry.

Despite much debate among scholars as to just what Saussure meant by *language, langue*, and *parole*, the distinction has held firm throughout twentieth-century linguistics. It has been suggested that certain work in stylistics (e.g., by Saussure's disciple Bally) and in discourse pragmatics constitutes an attempt at a linguistics of *parole*, but it is not yet clear how any aspect of language, once it is systematized, fails to enter the sphere of *langue*. The human will remains in exile from linguistics, and *langue* (naturally somewhat evolved from Saussure's original conception of it) continues to be the object of study of virtually every approach to which the name 'linguistics' is accorded (see Sect. 4).

4. *Langue* as a Social Fact

Saussure's insistence upon the social nature of *langue* grew during the years in which he lectured on general linguistics, largely at the expense of psychologically based considerations. Again, this may be tied in part to the need to establish synchronic linguistics independently of the dominant post-Humboldtian psychological establishment. The young science of sociology embodied the spirit of positivism, with which it shared the same recognized founder, Auguste Comte (1798–1857). Positivism was coming to be equated with scientificness in general thought,

75

making classical psychology appear old-fashioned and metaphysical. For the sociologists, Wundt's *Völkerpsychologie*, based on nonempirical generalizations (and more akin to what today would pass as philosophy of mind, not psychology) was already unacceptably passé.

Much ink has been spilled regarding the degree to which Saussure's conception of language was directly influenced by work in sociology, particularly by Emile Durkheim (1858–1917) and Gabriel Tarde (1843–1904). Saussure's former student and lifelong intimate Antoine Meillet (1866–1936; see also) was closely allied with Durkheim and his journal *L'Année sociologique*; and there is often a close correspondence between Saussure's and Durkheim's use of terms like 'social fact' and 'collective consciousness.' But since Saussure never cites Durkheim or Tarde (he was after all teaching a course, not writing a book), support for any claim of direct influence is lacking.

In Saussure's view, *langue* is a 'treasury' or 'collection of impressions' that is 'deposited' in identical form in the brain of each member of a given speech community. He uses the metaphor of a dictionary, of which every individual possesses an identical copy. What the individual does with this socially-shared system falls entirely into the realm of *parole*. This distinction (which was not yet clear to Saussure at the time of his first course in general linguistics of 1907) differentiates Saussure's dichotomy from that between 'competence' and 'performance' established in the 1960s by Noam Chomsky (1928–). Chomsky explicitly related competence with *langue* and performance with *parole*, though in actual fact the analogy was only partial: for Chomsky, competence (derived from innate universal grammar) is mental and individual, and performance the locus of its social actuation. Furthermore the considerable differences between Saussure's orientation toward language as a semiotic system and Chomsky's toward competence as a mental faculty make any such equations difficult.

Saussure's views on the social nature of language have had a great resonance in linguistics and many other fields. By the mid-1930s it was commonplace to equate 'synchronic linguistics' (indeed, 'scientific linguistics') with 'social linguistics,' and to include under this heading the work of Meillet and his many European disciples, including Alf Sommerfelt (1892–1965; and Joseph Vendryès (1875–1960; the American structuralists Leonard Bloomfield (1887–1949; and Edward Sapir (1884–1939; see *Sapir, Edward*); and even the 'social behaviorists' (or 'pragmatists)' John Dewey (1859–1952) and George Herbert Mead (1863–1931). Bloomfield in particular exploited the power of the social as an antidote to the psychological (or 'mentalist') approach at the time of his conversion from Wundtian social psychology to empirical behaviorism. Beginning in the 1940s dialect

geographers such as Raven McDavid (1911–1984; see also *McDavid, Raven Ioor, Jr*) began to realize the crucial importance of social factors in linguistic production; around the same time, the sociologist Paul Hanly Furfey (1896–1992) began training students jointly in the techniques of social class measurement and descriptive linguistics. By the early 1950s inquiry combining empirical sociological and linguistic techniques was underway, to be refined significantly by William Labov (1927–) (see *Labov, William*) and others in the 1960s.

In terms of Saussurean traditions, sociolinguistics pursues the Saussurean view of the social nature of *langue*, while Chomskyan generative linguistics (to which sociolinguistics has stood in irreconcilable contrast for a generation) pursues the Saussurean view of the mental and abstract nature of *langue*. An eventual reconciliation of this split—to which a deeper understanding of Saussure's thought may provide a clue—would certainly constitute a major breakthrough in the understanding of language.

5. *Langue* as a System of Signs: Semiology

The semiological conception of language as a collection of signs (a sign being understood as the collation of a signifying word and a signified concept) was anticipated in the philosophy of Aristotle (384–322 BCE), elaborated by the Stoics, and reached its summit in the 'speculative grammar' of the twelfth century. But starting in the fourteenth century, the view of language as a sign system began to cede pride of place to that of language as a social institution, an approach more characteristic of Plato (ca 429–347 BCE), the diffusion of whose works defines the new era of humanism that led to the Renaissance. The semiological perspective was never entirely lost, and would resurface notably among the seventeenth-century British empiricists. But the 'conventional' perspective with which it coexisted periodically overshadowed it, and the early nineteenth century was one such period, when abstract systems disembodied from human activity ceased to be of central interest.

As noted in Sect. 3 abstraction and disembodiment would reemerge as part of the 'scientific' spirit of the later nineteenth century; and it is thus no great coincidence that the 'semiotic' perspective on language was reopened independently by Charles Sanders Peirce (1839–1914) in the USA. Pierce's work in this area, like Saussure's, went unpublished during his lifetime, and was not seriously revived by philosophers until the 1930s. Only in the 1950s and 1960s were attempts made at unifying Saussurean 'semiology' (practiced mostly by European linguists) and Peircean 'semiotics' (practiced mostly by American philosophers) into a single paradigm, under the organizational leadership of Thomas A. Sebeok (1921–).

For Saussure, the network of linguistic signs which constitute *langue* is made up of the conjunction of a *significant* ('signifier'), understood as a sound pattern deposited in the mind, and a *signifié* ('signified'), a concept that is also deposited in the mind. Saussure compares them to the front and back of a single sheet of paper. It is important to note that the signifier is wholly distinct from the actual uttered word, as is the signified from the actual physical thing conceived of (if one exists). Although the distinction between concept and object has existed since antiquity, that between sound pattern and actual sound is Saussure's own contribution, of which some have seen a foreshadowing in the hypothetical 'sonant coefficients' of his early *Mémoire*.

Saussure predicted that *sémiologie*—the study of signs both within and outside of language—would have linguistics as its 'pilot science' (a further challenge to psychology, for the semiological domain is precisely where language is most explicitly mental), and indeed this came to pass in the founding of modern semiotics discussed above. But while linguistics has furnished the paradigmatic model for semiotics, the impact of semiotic inquiry upon linguistics has been slow in coming, with a certain acceleration perceptible in the last decade.

The one place where linguistics has been profoundly affected is in the nearly universal acceptance of Saussure's concept of the signifier as an abstract sound pattern. This view became the cornerstone of the concept of the phoneme as elaborated by Jan Baudouin de Courtenay (1846–1929) and Mikolai Kruszewski (1851–1887) in Russia, and subsequently by N. S. Trubetzkoy (1890–1938) in Vienna and Roman Jakobson (1896–1982) in Brno and Prague; Daniel Jones (1891–1967) in the UK; and Kenneth L. Pike (1912–2000) in the USA, to name only the most prominent figures (see *Firth, J. R.*) It resulted in the banishment of experimental phonetics from linguistic inquiry in favor of more abstract phonology, based not upon physical differences of sound, but on the ability to distinguish between concepts (see Sect. 8). The distinction between a physical 'etic' level (from phone*tic*) and an abstract 'emic' level (from phone*mic*) would be extended to every level of linguistic structure, and would become a hallmark in particular of postwar American linguistics.

6. The Arbitrariness of Linguistic Signs

As with the semiological nature of language, the arbitrariness of language—the fact that a signifier like the series of sounds /p a j/ has no internal connection with the concept of a 'pie' which it signifies—reflects an ancient doctrine that had never fallen very far from the center of debate about the nature of language up through the end of the eighteenth century. Though not a direct concern for most of the historical linguists of the nineteenth century, the ancient debate between *physis* 'nature' and *nomos* 'convention' in the establishment and operation of language had been revived by Whitney and the Humboldtian psychologists, with Whitney's views of language positioned on the side of *nomos* and the Humboldtians' on the side of *physis*. Saussure, who at age 21 had met Whitney and greatly admired his work, doubtless encountered the debate there.

Saussure's precise formulation of the linguistic sign allows him to situate arbitrariness—which he called the 'first primary concept' of linguistics—precisely at the conjunction of signified and signifier, just as presented in the first sentence of the preceding paragraph. This represented an advance over most earlier formulations of arbitrariness, which (despite Aristotle) focused upon the relationship between the sign as a whole and the real-world objects conceptualized in the signified. Unfortunately, the *Cours* is not consistent in its presentation of arbitrariness, and quickly falls back into the older schema. Another problem with the presentation in the *Cours* is that the arbitrariness doctrine is first encountered in radical form in a very tense, strongly worded, and memorable section; then only later is this tempered with a section on relative arbitrariness that is often ignored, but without which Saussure's conception of language is inaccurately understood. Saussure's point in the later section is that while signifiers are always arbitrary relative to signifieds, they can be motivated relative to other signifiers. Thus, for example, the French numbers *dix-neuf* '19' and *vingt* '20' both show arbitrariness between signifier and signified, yet *dix-neuf* is motivated relative to the numerals *dix* '10' and *neuf* '9' which compose it, hence *dix-neuf* is relatively arbitrary while *vingt* is radically so. (This is connected to Saussure's distinction between syntagmatic and associative relations, discussed in Sect. 8) Cases of onomatopoeia, where there seems to be a motivated relationship between signifier and real-world analog, are dismissed as not really part of linguistic systems.

The fact that the *Cours* presents the radical version of arbitrariness first and most forcefully led to its assuming the status of dogma in twentieth-century linguistics (though undoubtedly it also appealed to something deeper in the Zeitgeist). It is one of the first views of language to which budding linguists are exposed in introductory courses and textbooks, often as one of the design features of language identified in 1958 by Charles Hockett (1916–). Like most dogmata, the radical form of arbitrariness is counterintuitive and requires a certain faith beyond what reason can sustain. Also, it is not always observable in the practice of those who preach it, particularly because of the influence of Jakobson, who beginning in the early 1930s mounted a

sustained attack on radical arbitrariness through his work on markedness, child language acquisition, and aphasia, which suggested that linguistic elements differ in naturalness. Jakobson was to have a significant impact upon Chomsky, Joseph Greenberg (1915–), and many others, with the result that language is not treated as exhibiting anything like the radical arbitrariness of the dogma. Besides Jakobson, arbitrariness was problematized by Louis Hjelmslev (1899–1965), Émile Benveniste (1902–1976), and numerous others in a series of attacks on and defenses of the Saussurean view (often poorly represented) appearing from 1939 to about 1947.

7. The Linearity of Signifiers

After arbitrariness, the second primary principle of linguistics for Saussure is that linguistic signifiers are 'linear,' in the sense that, because they have a temporal existence, they represent a dimension that is measurable only as a line. This is one of the more mysterious of Saussure's ideas, in that he never made clear to what he was opposing it (he notes that it is obvious to everyone, but that its implications have not been appreciated). Linearity is part of what distinguishes spoken language as 'real' language, as opposed to writing, a secondary representation that is not necessarily linear (see Sect. 2); and it is what allows us to analyze connected discourse into meaningful units. One also detects a hedging on the inherent psychologism of the semiological view of language as consisting of perfectly juxtaposed signifiers and signifieds: Saussure here insists that signifiers exist in a completely separate dimension.

This principle has given rise to many interpretations. Jakobson formulated his doctrine of distinctive features in phonology—the idea that phonemes are not monoliths, but consist of bundles of features existing simultaneously—as part of a critique of the linearity of the signifier. Others have argued that Saussure's principle is not in disharmony with the concept of constituent features, but rather was intended (a) to deny the accumulation of signifiers, not their decomposition (a distinction which depends upon what one classifies as a signifier), (b) to insist that, however constituted, signifiers cannot be conceived apart from the dimension of time, and (c) to prepare the ground for the introduction of syntagmatic relations (see Sect. 8).

8. Syntagmatic and Paradigmatic Relations: *Langue* as Form, Not Substance

Saussure distinguished between the 'syntagmatic' relations a linguistic element has with the elements preceding and following it in an utterance, and 'associative' (now usually called paradigmatic) relations it has to other elements with which it shares partial identity, but which do not occur in the particular utterance at hand. For example, in the sentence *Crime pays* the element *crime* has a syntagmatic relationship with *pays* that determines, among other things, their order relative to one another and the fact that *pays* has the inflectional *-s*. At the same time, *crime* has paradigmatic relations with countless other elements, including the inflectionally related *crimes*, the derivationally related *criminal*, the conceptually related *misdemeanor* (and the conceptually opposite *legality*), and the phonetically related *grime*. As the last example suggests, each sound of the word *crime* /kraim/ has paradigmatic and syntagmatic relations with at least the sounds around it: /k/ is paradigmatically related to the /g/ that could in principle replace it; and syntagmatically related to the following /r/, since in English the presence of /k/ as the initial element of the word immediately restricts the following sound to /l r w/ or a vowel.

Saussure notes that the two types of relations, which correspond to different types of mental activity, contribute in different ways to the 'value' of the sign. In particular, the paradigmatic relations generate a negative value: the identity of the /r/ in /kraim/ is essentially that it could be, but is not, /l w/ or a vowel. This is important because the actual sound that represents /r/ can differ dramatically from one English dialect to another (being rolled, flapped, retroflex, etc.); but the actual sound content does not matter, so long as /r/ is kept distinct from the other sounds to which it is associatively related. *Langue*, Saussure insisted, is form, not substance.

Before Saussure, the syntagmatic relations of morphemes within a given utterance were certainly recognized as a matter of linguistic concern, though relatively neglected. But there was little or no precedent for the idea suggested by the *Cours* (implicitly if not explicitly) that there exists a syntax not only of words, but of sounds, meanings, and the relations uniting them; or that every time a sound, word, or meaning is chosen, a vast network of related elements is summoned up in absentia. The latter concept in particular set the study of language on a new course of abstraction that did not rely on psychological theorizing, but remained internal to language.

In many ways, the Saussurean notion of paradigmatic and syntagmatic relations would become the hallmark of twentieth-century linguistics: first, because it proposed that a single principle of structure unites all the levels at which language functions—sound, forms, and meaning; secondly because it suggested a way of analyzing language that would not depend on a simple listing of elements with their 'translation' into either another language or some sort of philosophical interpretation. Elements could henceforth be analyzed according to the relations they maintained with other elements, and the language could be understood as the vast system—not of these elements—but of these relations. This was the point of departure for structuralism (see Sect. 9).

To a large extent, the distributional method developed by Bloomfield is a working out of this Saussurean notion, with special emphasis on the paradigmatic relations. With the work of Bloomfield's student Zellig S. Harris (1909–1992) the syntagmatic relations assumed a status of equal importance, and with Harris's student Chomsky, overriding importance. (Regarding word order, Saussure's view is that the syntagmatic relations constitute that part of syntax which is predetermined—like the use of a third person singular verb form after the singular subject *crime*—and so a part of *langue*; while the rest of syntax, being subject to free combination, is relegated to *parole*.)

9. The Systematicity of *Langue*: Structuralism

Certainly the most wide-reaching Saussurean intellectual tradition, both within and outside of linguistics, derived from Saussure's characterization of *langue* as a wholly self-contained network of relationships among elements which as discussed above, have no positive content or value, but only the negative value generated by their differing from one another. Like most of his contemporaries, when Saussure thought of language he thought first of sounds and their combinations, and extrapolated outward from that level. The study of sounds had for several decades been a battleground between those who, later in the twentieth century, would be called the 'phoneticians,' proponents of an extreme form of positivism who believed that the key to understanding language lay in ever more precise measurement of sound waves and vocal apertures; and those who would now be called 'phonologists,' who preferred to operate on a more abstract (and traditional) plane, dealing with classes of sounds rather than the minute differences within classes. But the phoneticians were steadily gaining prestige, since their positivistic approach had the characteristic look of modern science.

As noted in Sect. 4, Saussure was attracted to positivism, but within limits. If psychology represented the Scylla of hyperrationalism, experimental phonetics was the Charybdis of hyperempiricism, equally to be avoided. Perhaps more so: whereas Saussure never attempted a complete divorce of language from the domain of the mind, his characterization of *langue* as a network of pure relations, of form and not substance, succeeded in marginalizing phonetics to the point that within a few decades it would retreat to the position of an auxiliary discipline to linguistics. The term *phonème*, used by Saussure as early as 1878 (five years after its coinage by A. Dufriche-Desgenettes, 1804–1879) to denote an abstract unit representing sound, but never actually defined by him, was taken up by Boudouin de Courtenay and Kruszewski and joined to an essentially Saussurean conception: 'phoneme' became

the name for Saussure's abstract mental sound pattern, identifiable as the minimal unit of sound capable of changing the meaning of a signifier in a language. It eventually became the basis for further, related new concepts: the morpheme (coined by Baudouin de Courtenay) or moneme (minimal unit of meaning), tagmeme (minimal meaningful unit of syntax), toneme, and so on.

The full implications of Saussure's view of *langue* were localized in Prague, principally by Trubetzkoy, who elaborated complete phonological schemata for a panoply of languages from all over the world; and Jakobson, who extended the implications of 'functional' phonology to other domains of linguistic (and literary) inquiry. But strikingly similar projects were underway in other quarters: in the USA with Bloomfield, who saw himself as at least partly under the influence of Saussure (in a 1945 letter he described his major work *Language* as showing Saussure's influence 'on every page'); in Denmark, with the overtly Saussurean glossematics of Hjelmslev; in France, where Meillet had transmitted the Saussurean perspective to a whole generation of students, including André Martinet (1908–1999); Gustave Guillaume (1883–1960); and Benveniste. All the lines of affiliation among these 'schools' are not yet clear. But their work came to define the mainstream of linguistics in the twentieth century, and all of it assumes the conception of *langue* set out in the *Cours*.

The idea that language forms a self-contained system justified the autonomy of linguistic study not only vis-à-vis phonetics, but every other discipline as well, including psychology, anthropology, and sociology (the latter, again, was never deemed a threat). The only discipline under whose aegis it hypothetically fell was semiology, but even had semiology existed, the status of linguistics as its pilot science meant that it yielded its autonomy to no other field. Indeed, between the 1940s and the 1960s most fields of human knowledge came under the domination of 'structuralism' (a term first used in linguistics around 1928), understood in this context as the extrapolation out of linguistics of Saussure's concept of *langue* as a self-contained system of syntagmatic and paradigmatic relations among elements of negative content (see Joseph 1994). Its most widely heralded application was in the field of anthropology, by Claude Lévi-Strauss (1908–), who discovered Saussure in 1942 in a course taught by Jakobson. Other areas and their most prominent structuralist practitioners include: biology, Ludwig von Bertalanffy (1901–72) and C. H. Waddington (1905–1975); literary theory, Roland Barthes (1915–1980); Marxist theory, Louis Althusser (1918–1990); mathematics, 'Nicholas Bourbaki' (the pseudonym of a group of French mathematicians); psychoanalysis, Jacques Lacan (1901–1979); and psychology (where the groundwork for it had already been laid by the concept of

Gestalt), Jean Piaget (1896–1980). The rejection of structuralism by such figures as Jacques Derrida and Michel Foucault (1926–1984; see *Foucault, Michel*), which became widespread as part of the French student revolts of 1968, launched the 'poststructuralist' era, whose very name indicates that the Saussurean tradition remains an active force even when shaping the direction of reactions against it.

Within linguistics, the effects of poststructuralist thought are only beginning to be felt; the field in which structuralism began is the last to let it go. Precisely at mid-century the great British linguist J. R. Firth (1890–1960) was able to state that 'Nowadays, professional linguists can almost be classified by using the name of de Saussure. There are various possible groupings: Saussureans, anti-Saussureans, post-Saussureans, or non-Saussureans.' As we approach the twentieth-century's end, the only change one is tempted to make to Firth's statement is to remove 'non-Saussureans,' as it is doubtful that any survive. All work on or against language as an autonomous, self-contained system—and this includes work in generative grammar, universal–typological linguistics, discourse pragmatics, and sociolinguistics—falls squarely within the most important of Saussurean traditions.

Social Psychology

W. S. Bainbridge

Social psychology is an interdisciplinary academic field, lying between psychology and sociology, with less substantial connections to economics and to literature. At many universities, competing social psychology courses are taught in both the psychology and sociology departments, and on rare occasions joint departments in social relations have been founded. The division between psychology and sociology is so extreme that it has become fashionable to speak of 'two social psychologies' rather than one. Despite its fragmentation, social psychology speaks with a strong voice on the importance of language in human relations, and many of its theories and research findings should be of direct concern to linguistics. Several essays in this *Encyclopedia* examine in detail aspects of the social psychology of language, and this essay provides an overview. After sketching the structure of the field, a sampling of major language-related topics will be considered: the social psychology of speech, attitudes, symbolic interactionism, meaning, and microsociology.

1. The Structure of Social Psychology

Stephan and Stephan (1985) say that sociological social psychology concerns social experience stemming from individuals' participation in groups, social interaction, the effects on both of these of the cultural environment, and the emergence of social structure from interaction. In contrast, psychological social psychology focuses on the thoughts, feelings, and

behaviors of individuals as influenced by others. In sociology, Stephan and Stephan contend, two distinct schools of thought exist: symbolic interactionism, which holds that reality is socially constructed through the meanings people communicate, and the personality and society perspective, which emphasizes the attitudes and values that individuals derive from their cultures. Psychological social psychology seems even more diverse, including social learning theory, exchange theory, role theory, and attribution theory.

While such a typology can have heuristic functions, no single conceptual division of the field has achieved wide consensus. Not only is it difficult to map social psychology at a given point in time, but as Sahakian's review of the history of the field proves, its contours and divisions have changed over the decades. A. M. McMahon and a number of other authors have argued that social psychology of all varieties experienced a crisis in the late 1970s, when many critics charged that the field had lost sight of fundamental questions, and the knowledge gained by each successive research project seemed to illustrate the law of diminishing returns.

George Homans frequently remarked that human beings must have always known the chief truths concerning social behavior, or else they would not have been able to sustain successful relations with each other. If true, this observation sets sharp limits to the achievements possible for academic social science. Prior to the late 1970s, however, social psychologists had made striking claims for a number of rather counterintuitive theories, and part of the crisis that followed may merely have been their empirical disproof.

McMahon (1984) says that psychological social psychology was dominated by two classes of theorizing: trait theories of individual behavior and field theory. Trait theories assert that social conditions shape individuals, giving them distinct personalities or attitudes that become fixed and thus render behavior consistent across many very different situations. When human behavior was found to be significantly inconsistent, and attitudes refused to stabilize in study after study, trait theories lost ground. Field theory asserts that the proper unit of analysis is the social system, but beyond this its advice has not been clear its influence has faded as its terminology has been replaced by fresher metaphors.

Sociological social psychology, for McMahon, either borrowed its perspectives from psychology, in which case it suffered the same crisis, or drew upon the often compatible sociological schools of thought known as 'symbolic interactionism' and 'structural functionalism.' In textbooks of a generation ago, symbolic interactionism was used to explain individual-level phenomena, while structural functionalism explained phenomena on the societal level. Suppo-

sedly, society was a structure of institutions, organized around a coherent set of values and beliefs, that served vital functions for the entire system. Individuals were socialized, greatly through symbols exchanged during social interaction, to play their necessary roles in the institutions. However, in the 1960s structural functionalism crashed, its theories seeming either factually wrong or vacuous, and its relative political conservatism was no longer attractive to the increasingly radical sociologists. Symbolic interactionism has retreated from its partnership with the now bankrupt structural functionalism, and it continues to be a vital school of thought recruiting new scholars and publishing at a great rate. Yet its theories have never been particularly adapted to unambiguous empirical testing, and the increasing quantification and empiricism of the main journals shunted symbolic interactionism over to the sidelines.

2. The Social Psychology of Speech

A few older textbooks on social psychology contain distinct sections on language, notably the excellent texts by Roger Brown (1965) and by Krech et al. (1962) but most textbooks of the late 1980s and early 1990s disperse their material on language across several chapters ostensibly devoted to other topics. For example, studies on interpersonal influence are found throughout these texts, offering many insights that might be applied to linguistic analysis of accommodation (see *Speech Accommodation*), the adjustment of speech to match that of persons with whom one is speaking.

The study of psychopathology has particularly generated theory and research concerning language. Psychotherapy, the talking cure, assumes that emotional problems are sufficiently language-rooted that the insight or catharsis that can come from talking about them is curative. The theory of the double bind, to mention a specific example, asserts that mental problems can arise from contradictory messages imposed on a powerless person by a powerful one. One form of therapy, albeit a deviant one, was explicitly linguistic in nature, the general semantics movement that asserted that all human social and emotional pathologies resulted from misuse of language. Research has also been conducted on deception, the conscious use of language to misinform the listener, including a large body of studies on the socalled Machiavellian personality who habitually lies (Christie and Geis 1970, Hyman 1989).

Social psychologists have learned about language not only by studying it, but also by perfecting research methods that rely heavily upon it. For example, interviewers have been forced to learn how to maximize rapport with their research subjects, thus gaining general insights into how successful communication can be achieved. Richard A. Berk and

Joseph M. Adams (1970) have suggested four principles of establishing rapport with respondents who are apt to be suspicious of the researcher: always be honest, be prepared to inconvenience oneself as a sign of commitment, always keep one's word, and speak in as flattering terms as possible, consistent with plausibility.

Berk and Adams have also listed techniques for establishing respect and acceptance. While it is important for an interviewer dealing with subjects who speak a different language to communicate in their terms, the interviewer should not adopt the slang style of the subjects unless it is very natural for the interviewer. The subjects may appreciate the special effort the interviewer makes to learn their language, but they know the interviewer is not a member of their group and may be offended by a pretense of membership. Other language-related techniques include remaining unshaken even when one hears things that are very shocking to the researcher's personal standards, and occasionally revealing some intimate facts about oneself in recognition that really successful communication requires a reciprocal relationship between the speakers.

Raymond L. Gordon (1969) has identified eight factors that inhibit communication in interviews: competing demands for time made by activities outside the interview, threats to the person's ego that various topics may constitute, etiquette rules that prohibit saying certain kinds of things in public or to certain kinds of people, the pain of recounting past traumatic experiences, simple forgetting, confusion about the chronological order of events, inferential confusion about the meaning of events, and unconscious behavior patterns that set hidden agendas for the conversation. The best antidotes to these inhibitors are eight facilitators: the respondent's desire to fulfill expectations, the recognition he or she seeks from the interviewer, altruistic appeals that stress the ultimate values served by the interview, sympathetic understanding of what the person expresses, the new experience that an interview affords, emotional catharsis, the opportunity to place memories and feelings in a meaningful context with an intelligent listener who asks guiding questions, and extrinsic rewards such as money paid for talk.

3. Attitudes

Perhaps the most widely used concept in psychological social psychology is *attitude*, often defined as the positive or negative evaluation of an object, with anything, tangible or intangible, capable of being the object of an attitude. As the term is generally used, each person is presumed to possess a large number of attitudes that can be expressed almost instantly in words and that are the key determinants of behavior with regard to the object. People who say they favor

political party X can be expected to vote for it; people who express positive attitudes toward particular foods are likely to eat them. The standard way of measuring attitudes is through self-report questionnaires or interviews, and the underlying assumption of this research is that attitudes are coded verbally in the brain, thus making them linguistic phenomena.

Linguists have begun systematic research on attitudes towards speech styles (see *Style*), in light of the fact that speakers and dialects are often evaluated harshly if they do not meet some set of standards applied by listeners. Standard psychological experimental methodology has been applied to this topic, through the matched guise technique (MGT), described by Peter Ball and Howard Giles (1988). Respondents are played a set of recordings of voices and asked to judge the speakers' capabilities, personalities, emotional states, and various other social and linguistic characteristics. The challenge in such a method is to control for differences in the speakers' voices that are unrelated to the independent variable in question. In MGT, speakers are chosen to make the recordings who are capable of speaking in two distinctly different ways, for example equally fluently in French or English, thus matching all voice characteristics other than the one under examination.

Perhaps the classic example of social psychological research on attitudes is the work on attitude change that was performed at Yale University around 1950, still relevant and constantly being extended in the 1990s. Two of the experiments done at Yale by Carl I. Hovland and his associates will demonstrate the wide range of language-related phenomena that were studied, one concerning the credibility of communicators, and the other exploring the role of public proclamations in stabilizing attitudes. In an experiment reported by Hovland et al. (1953), a recorded lecture about juvenile delinquency was played to high school students who were asked to judge how fair it was. The first of three experimental groups was told that the speaker was a judge in a juvenile court, someone who was a real expert on the topic, and highly respectable as well. A second group thought the speaker was an ordinary member of a radio program's studio audience, and a third group was told that the speaker was a former juvenile delinquent currently awaiting trial on a charge of drug peddling. The judge was considered fair by 73 percent of the subjects, and 63 thought the ordinary person was fair, but only 29 percent gave a favorable rating to the accused drug pedlar. The vast literature of similar studies that have followed on from the Yale research support and give scientific specificity to the commonsense notion that speech has a variable impact on listeners, depending upon who speaks it.

The second attitude change experiment divided student respondents into two groups who were given a pair of lectures on the issue of the voting age, which

was 21 years old at the time of the study. In the first phase of the experiment, the subjects heard a speech giving one side of a debate on voting age. Then the students were asked whether they agreed or disagreed with the following statement: 'The voting age should be reduced from 21 years to the draft age of 18 years.' After that, they all wrote an essay, giving their views on the voting age debate. The second phase consisted of another speech, giving the other side of the voting age debate. Finally, the students were asked again to state their view on whether the voting age should be reduced from 21 to 18.

The experimental manipulation concerned the essay the student wrote at the end of the first phase. Half of the students were told to sign their essays and were informed that they would appear in the next issue of the school newspaper, while the other half of the respondents were left to believe that their essays and opinions were private. The researchers hypothesized that making a public commitment to an opinion reduced the chances that a person would change his or her views subsequently. Indeed, among the group that signed their essays and believed they would be published, only 14 percent changed their opinion to agree with the second speaker, while in the control group, 41 percent did so. Thus, expressing an attitude in public strengthens the individual's commitment to it.

Research on attitudes is conducted at such a high rate in the late twentieth century, that the *Annual Review of Psychology* summarizes it regularly (Cooper and Croyle 1984, Chaiken and Stangor 1987, Tesser and Shaffer 1990). Yet serious questions remain about the efficacy of the concept. In particular, questions continue to be raised about the connection between attitudes and behavior (see *Attitudes and Behavior*), and many studies indicate that what people say and what they do are quite different things. Certainly the concept of attitude asserts a theory about the power of language, and much research on the topic will be of interest to linguists.

4. Symbolic Interactionism

Symbolic interactionism is a distinct school of thought, acknowledging a unified heritage that many say began with George Herbert Mead. Although some symbolic interactionists have accepted the canons of positivist science, others, notably Herbert Blumer, believe that social reality is too multifaceted and fluid to be captured in a few rigid hypotheses. Some of the most influential members of this school, Erving Goffman (see *Goffman, Erving*), for example, offer suggestive interpretations of the meaning of human behavior and symbolic expression, but refuse to subject them to any process of unequivocal evaluation. To that extent, symbolic interactionism

is more like poetry or music than it is like the natural sciences.

Some writers distinguish two brands of symbolic interactionism, the Chicago School, which stresses interpretation of humanly constructed meanings to the exclusion of hypothesis testing, and the Iowa School, which allows the possibility of logically framing and empirically testing somewhat general statements about human behavior. But in all its manifestations, symbolic interactionism offers a sharp critique of the currently dominant approach in the central sociology journals, which stresses the computerized analysis of frequently superficial numbers far removed from the richness of human meanings.

Among the early concepts that continue to have great influence is definition of the situation, proposed by Thomas and Znaniecki in 1918. The meaning of something does not immediately announce itself to us, but must be read into every situation, typically on the basis of the culture shared by participants and prior experiences of the individuals. To some extent, such definitions are arbitrary, and there are always alternative definitions that fit a situation equally well. But once a definition has been adopted, it conditions people's actions, feelings, and further perceptions.

Among the most important entities that requires definition is the self. A glance at an English dictionary reveals that *self* appears in literally hundreds of compounds, from *self-abandoned* to *self-worship*, and it primarily serves to indicate reflexivity. As George Herbert Mead analyzed it, this reflexivity is both subject and object, the first person in both nominative and objective cases, the *I* contemplating the *me*. Clearly, there are several ways one might analyze *self* linguistically, and in various usages it is frequently listed as pronoun, adjective, noun, and even verb. As a noun, it is an abstraction referring to the entire person of an individual. Symbolic interactionists have both examined the concept closely and employed it to great effect in their analyses of individual behavior and of society. As Hazel Marcus and Elissa Wurf (1987) noted, social psychologists of several varieties have come to see self-concepts as dynamic, multifaceted, and implicated in social phenomena of all kinds.

Among the ways a self can manifest itself is through the playing of roles, and role theory (see *Role Theory*) has been developed and applied by literally hundreds of symbolic interactionists. Language enshrines many roles, such as 'father,' 'mother,' 'priest,' 'judge,' and 'teacher.' The complete set of roles in a society provides a kind of social grammar, defining how persons (rather than words) are supposed to interact, and they are among the most thoroughly linguistic of social phenomena. Many sociologists argue that social roles are scripted by society and define *role* as 'a set of expectations

governing the behavior of persons holding particular positions in society; a set of norms that defines how persons in a particular position should behave' (Stark 1989: 686). Symbolic interactionists have given rather more stress to the capacity of individuals to script their own roles, for example, through constant *impression management* intended to give the most favorable impression of oneself to others, and to the way that the roles in a particular social group are constantly undergoing change. In the extreme, it can be argued that the self is nothing more than the set of roles played by a given person.

The self comes into existence through interaction with others, and the other, as an alternate self, comes into existence reciprocally through the same process. Important in symbolic interactionism is the concept of the *generalized other*, a kind of indefinite second person that represents the shared perspective of all the particular others who interact with the self. By taking that perspective, in the imagination, a person can view himself from outside as it were, thus attaining a clear concept of self. At one level, the generalized other can represent all of humanity minus one, but there also can exist several more limited generalized others, including groups that serve as reference points for the definition of the self.

A reference group is a category of persons, real or imaginary, toward whom the individual orients his behavior and which he uses to define himself. Often, the individual desires the approval of the reference group and tries to become a worthy member of it. A negative reference group, however, is a category of people one wishes to disassociate from, and one method to achieve this it to broadcast the twin message that the traits of the group are abhorrent and that one possesses very different traits. For years, reference group theory has been influential in business marketing research, and advertising is often designed to communicate messages associating a product with groups that are positive reference groups for many consumers.

Early in the twentieth century, symbolic interactionism greatly influenced educational theory in the United States, and in diluted and often unrecognized forms, it continues in the 1990s to shape discourse about the means by which good citizens and responsible adults are created. Many community leaders, social workers, and journalists talk the language of symbolic interaction without necessarily understanding its technical meaning or the relatively distinct philosophy of life embodied in it. In sociology, symbolic interactionism has been important in shaping conceptions of values, and it has contributed to our understanding of the role of symbols in social conflict through labeling theory of deviant behavior and the analysis of social movements as symbolic crusades.

5. Meaning

Not surprisingly, *meaning* is one of the most difficult words to define, especially as it is used in social psychology to refer to humanly constructed frameworks for perception, emotion, and action. A dictionary may say that meaning is what is conveyed by language, but how this 'what' exists apart from the language that conveys it is not clear, and the meaning of *meaning* has been the special focus of ethnomethodology, attribution theory, and branches of semantics that spread into social psychology.

Ethnomethodology (see *Ethnomethodology*) is a school of sociology concerned with how human beings make sense of their everyday lives, and like symbolic interactionism, it stresses the processes by which people achieve definitions of objects, roles, and even the internal states of their own minds. Of particular interest to linguists, ethnomethodology was in great measure the source of the movement known as 'conversation analysis' (see *Conversation Analysis*). Ethnomethodology is distinct from symbolic interactionism both in arising from German philosophical roots rather than American ones, and for giving rather greater emphasis to the internal subjectivity of the individual, and less to the role of the other. Indeed, while symbolic interactionist George Herbert Mead was concerned with how other people participate in the building of an individual's self, ethnomethodological precursor Alfred Schütz wrote about how a person gains insight into other's subjectivity through consideration of his or her own.

Richard Hilbert (1990) has argued that ethnomethodology (including conversation analysis) should not be considered a part of social psychology because it transcends the distinction between microsociology and macrosociology, and yet with its emphasis on the contents of the human mind and its empirical emphasis on the details of interactions between individuals, it seems appropriate to consider it here.

A classic empirical study in the ethnomethodological tradition was Peter McHugh's (1968) experiment that ostensibly studied a new method of counseling. Each research subject sat alone in a room, speaking into a microphone about his personal problems and asking questions answerable by 'yes' or 'no.' After the counselor in another room responded, the research subject was supposed to say aloud what the answer meant to him, then proceed to present more of his problems and ask further yes–no questions. In fact, the yes–no answers were given according to a prearranged pattern, and had nothing to do with the questions asked. The fact that the subjects typically found the answers meaningful was interesting, but the study also allowed close examination of the framework people used to construct the meaning they believed they had found.

Many ethnoemethodological studies have concerned direction-giving of one kind or another. In one design, the researcher telephones various businesses, asking directions for how to come over but continually failing to understand them; this forces the unwitting research subjects on the other end of the phone to struggle to orient the caller in terms of landmarks or abstract principles like compass directions. A less intrusive method is to listen in on the radio messages used to dispatch taxicabs. One researcher merely observed what medical personnel said to patients who were awakening from general anaesthesia, words apparently chosen to reorient the person and prevent them from panicking and thrashing around.

Ethnomethodology is in great measure based on phenomenology, a philosophical tradition associated with Edmund Husserl. For example, a technique of philosophical analysis called 'reduction' can be adapted to the study of the meaning of concepts. In reduction, one contemplates a particular concept, noting all the characteristics that seem associated with it. Then one mentally examines each characteristic in the list, determining whether the concept in question could exist without it, and crossing the characteristic off the list if it could. Eventually, one arrives at an irreducible list of attributes of the concept in question, a pristine definition of it shorn of all nonessentials.

What is a telephone call? The phone rings, someone picks it up, and a person says 'Hello.' That's a phone call. But is the ring essential? No; there could be a flashing light, or other signal. Is some kind of signal necessary? Perhaps; that question needs further study. Is it essential for there to be something to pick up? No. Must there be someone on the other end of the line? Yes. Must that person be aware that there is somebody on this end of the line? Yes. Is the exchange of words necessary? Eventually, after close thought to resolve any ambiguities, reduction would produce the essential definition of *telephone call*. In their empirical research, ethnomethodologists force ordinary people to act out this procedure, or they watch them employing their *ethnomethods* to make sense out of natural problems of definition that present themselves in the world of everyday life.

In psychological social psychology, the 1970s and 1980s saw the emergence of a major approach to meaning called attribution theory. When it first emerged in the 1960s, attribution theory had some similarities to ethnomethodology; both stressed the ways people make sense of their surroundings and both made radical claims about the novelty of their findings. For example, attribution theorists frequently asserted that people do not know their own minds but infer their attitudes on the basis of observing their own behavior or being told by others how they felt.

A host of experimental studies seemed to confirm this diagnosis of human self-ignorance. Subjects given injections of epinephrine felt and behaved quite differently, depending on what they had been told the effects would be or on how the experimenter's confederate behaved. Subjects who had received a series of painful electric shocks could endure more or less further pain depending on whether they were told they had been assisted in tolerating the earlier shocks by a drug. Despite initial appearances, attribution theory turned out not to be one of the faddish excesses of the 1960s, but a solid contribution, and in the 1990s it can now be seen that much work before the 1960s actually laid the basis for the recent developments. Attribution theory focuses most closely on the social and psychological processes by which people define the causes of events, but its ideas are remarkably similar to those of contemporary symbolic interactionism, except supported by a far stronger empirical research program.

Another development in psychological social psychology that focuses on meaning is the research technique known as the 'semantic differential.' It consists of a set of paired opposites, such a good–bad and happy–sad, presented as questionnaire scales. The respondent is required to rate a concept on each of these scales, and statistical analysis then maps the concept along three dimensions: evaluation, potency, and activity. Widely used in a variety of studies conducted in many languages, the semantic differential is believed to measure the connotative meaning of terms. Very recently, as John Digman (1990) reports, the three semantic dimensions have been related to a system of five dimensions of personality that has achieved much consensus among psychologists: extraversion/introversion, friendliness/hostility, conscientiousness, neuroticism, and intellect. Digman further notes that the personality typologies employed both by psychologists and by ordinary people are rooted in language and may be little more than the system human language possesses for classifying human behavior.

6. Small Groups and Other Microstructures

At present, judging from course enrolments and book sales, the psychological brand of social psychology is more popular than the sociological brand, and thus perhaps it is more influential. However, much of the work done in sociology that could be called social psychology is given other names. Rodney Stark (1989: 682–3), among others, calls it 'microsociology,' which he defines as 'the study of small groups and of face-to-face interaction among humans,' to be contrasted with macrosociology, 'the study of large groups and even of whole societies.' Much microsociological research is performed in the field, for example, observational

studies of families, religious groups, or deviant subcultures, while psychological social psychology is more wedded to the laboratory and to the experimental method. Some varieties of microsociology eschew psychology altogether, if by 'psychology' is meant the study of the individual psyche, and focus instead on the structure of social relations in small groups and networks.

In both sociology and psychology, small group research (see *Small Group Research*) has been carried out vigorously for many decades. Groups establish norms concerning proper language; the status structure of groups often demands deferential or commanding language, and groups shape the language of members through cohesive social relations and the socialization of values. Among the research techniques developed to study communication patterns in small groups, interaction process analysis is notable not only for its great influence but also for providing a novel theory of the categories of speech.

Microsociologists have become increasingly dissatisfied with the concept of group, however, noting that many of the stable social relationships that affect the individual occur in open structures that might better be called 'networks.' Sociometry (see *Sociometry*) is the technique for studying social networks, and the measurement of linguistic influence across complex social structures has progressed considerably in recent years.

Some scholars, in both psychology and sociology, prefer to begin their analysis with the exchanges that take place between individuals, and exchange theory has become a prime rallying point for social psychologists who emphasize the economic nature of human behavior. Like symbolic interactionism, exchange theory focuses on the give and take that transpires between individuals, but it ignores symbols in favor of rewards, whether tangible or intangible. Thus, exchange theory appears to give a lesser role to language than do the other perspectives described above. In the extreme, as practiced by George Caspar Homans, exchange theory is thoroughly behavioristic, denying the importance of the subtle contents of the human mind, words included.

7. Conclusion

The diversity of social psychology is at once a blessing and a curse. Few practitioners are aware of the potentially great value of uniting social psychology with linguistics, and those few can at best create narrow bridges between their own particular subfields or schools of thought and scholarly linguistics. Thus, a convergence of social psychology and linguistics will be difficult to achieve. However, language plays such a tremendous role in so many branches of social psychology, and a variety of its

theories and research traditions have so much insight and information to offer linguists, that a marriage of the disciplines is worth promoting.

Socialization
C. B. Cazden

Socialization is the process of internalization through which human beings become members of particular cultures, learning how to speak as well as how to act and think and feel. The term 'language socialization' is used more often for the primary socialization that takes place during childhood within the family (for which Schieffelin and Ochs 1986, is the best short review); but it should also refer to secondary socializations throughout life to specialized forms and uses of language in school, community, and work settings.

Language socialization is a more inclusive term than language acquisition, emphasizing pragmatic as well as syntactic and semantic competence; it is the preferred term in linguistic anthropology, sociolinguistics, and culturally oriented psychology.

1. Relationships Between Language and Socialization

Language relates to socialization in three ways. First, language is the primary medium for socialization into culture; that is, there is socialization by or through language, where language is the means. Second, there is socialization for language, where situation-specific and culture-specific language use is the outcome. Third, there is socialization about language in the form of knowledge about, and attitudes toward, language forms and functions. While these three aspects of socialization occur together in real life, they are often studied separately, and by different research techniques.

2. Socialization Through Language

Language plays an especially important role in socialization because it is such a pervasive and orderly feature of everyday life in every culture (Sapir 1962). Three characteristics of language contribute to this role: its propositional nature makes possible explicit cultural instruction; its reference to the non-here-and-now permits the sharing of memories and knowledge of the past, plans for the future, and imagined worlds; its indexicality means that units of language, such as terms of address or speaking one dialect rather than another, point to culturally interpreted aspects of the nonverbal world. (Ochs 1990 discusses this last, and more subtle, relationship.)

3. Socialization for Language

Learning to speak is never simply a matter of learning a particular language or dialect—i.e., the words, syntactic patterns, and accent spoken in a particular community; it also involves learn-

ing multiple registers, i.e., particular ways of using language in particular settings within that community.

When one shifts registers, one also often shifts what one is talking about, and the values and beliefs implicit in those words. For this reason, Gee uses the term 'discourses' for 'forms of life which integrate words, acts, values, beliefs, attitudes, and social identities' (1996: 127; see *Discourse*). He then distinguishes primary and secondary discourses (including literacy in the latter), and also dominant and nondominant discourses according to their social prestige and power.

Even young children exhibit some register variation—for example, by speaking differently to adults or their peers (reviewed in Andersen 1990). For most people, secondary socialization in additional registers continues into adulthood, as they acquire new ways of speaking in new roles. Examples include the nearly universal, but culturally expressed, roles of student (Cazden 2001) or parent (Snow and Ferguson 1977); professions such as doctor or lawyer (Philips 1982); age-specific rhetorical styles such as 'the talk of the elders of bygone days' in Mexicano communities in the southwestern USA (Briggs 1986); and occasional oral tasks like chairing meetings, or conducting sociolinguistically appropriate interviews in a particular speech community (Briggs 1986).

Most research on language socialization is ethnographic. But experimental situations such as role playing can reveal register knowledge for roles never enacted in reality. Andersen (1990) provides both a research review of such knowledge in children, and a report of experimental research in which 4- to 7-year-old children gave a doctor puppet lower pitch and more imperatives and questions when talking to a nurse, and gave the nurse more polite requests to the doctor.

4. Socialization About Language

Socialization about language includes both knowledge and attitudes. One kind of metapragmatic knowledge is evidenced in the way speech is reported in narrative. Whereas 7- and 10-year-old children frame direct speech, usually with 'said,' 4-year-olds often provide no verbal framing but sometimes differentiate voices by pitch (Hickmann 1985).

Other kinds of knowledge become important when children enter school and confront the task of learning to read. Where alphabetic orthographies are used, learners must become aware of the sounds in oral language and their relationship to letters; and

even teachers, whose mental representation of language has been influenced by experience with written texts, may have to learn to distinguish the number of phonemes in a word from the number of letters (see *Speech and Writing*).

As with oral language, 'literacy socialization' is a more inclusive term than 'literacy acquisition': while the latter may refer only to learning to encode, decode, and comprehend print; the former points also to uses of reading and writing for different purposes in different settings.

Attitudes toward language can often be inferred from observations of which forms available in an environment are in fact learned, and from spontaneous comments about other people's oral or written language use. More systematic study of language attitudes requires more experimental techniques, often by social psychologists. One widely used technique is the matched guise in which subjects evaluate messages spoken in different languages or dialects but, unknown to the subjects, by a single speaker.

5. Environmental Influences on Language Socialization

There is general agreement that primary socialization occurs through participation, and through interaction between children and more mature speakers, both adults and peers. In fact, family and community settings for the virtually universally successful process of language socialization are often cited as the prototype of effective learning environments. While implicit immersion in language-related activities is certainly crucial, there is also evidence that more explicit tuition also occurs, e.g., in elicited imitation routines found in many cultures in which an adult will direct a child to say a word or phrase (Ochs 1990).

How secondary socializations can be aided in school is less clear, and educational controversies continue over the most effective combination of implicit immersion and explicit instruction. Heath (1983) gives a vivid picture of primary socialization in three communities that differ in race and social class, and an optimistic report of how teachers adapted their teaching for more effective secondary language socialization in school—including getting learners to 'become ethnographers' and study language use themselves.

In the study of language socialization, gender differences in ways of speaking—sometimes referred to as genderlects—are especially interesting because most children are exposed to both men's and women's speech during their primary socialization. Differential socialization cannot, therefore, be explained by differential exposure (Warren-Leubecker and Bohannon 1989).

6. Socialization and Resistance

Many writers on language socialization imply that language socialization is always successful as long as the learning environment is at least minimally adequate. But resistance does occur. Familiar examples are immigrant children resisting speaking the language of their primary socialization at home, if the language of the school is also the language of wider society, or nondominant dialect speakers resisting speaking a standard dialect despite its availability at school and on television.

Writing about the more general field of the socialization of cognition Goodnow (1990: 280) states: 'I seek an account of socialization that goes beyond saying that the individual must be regarded as agent or actor, or that influences are bi-directional... [E]ven if much of one's life is spent in puppet fashion, there remain at least the occasional times when one notices the strings and decides to cut them.'

Of all forms of learning, language is closest to one's social and individual identity; and that identity helps to account for both resistance and learning, and is also their result. In Sapir's words, 'In spite of the fact that language acts as a socializing and uniformizing force, it is at the same time the most potent single known factor for the growth of individuality' (1962: 19).

Sociolinguistics of Sign Language
C. Lucas

Natural sign languages are autonomous linguistic systems, independent of the spoken languages with which they may coexist in a given community. As sign languages are fully fledged autonomous linguistic systems shared by communities of users, the sociolinguistics of sign languages can be described in ways which parallel the description of the sociolinguistics of spoken languages. That is, the sociolinguistics of sign languages concerns the interrelationship of sign language and social structure. As with spoken languages, sign languages are at once used to communicate information and to define the social situation, i.e., to make statements about individual identity, group loyalties, and one's relation to one's interlocutors. The sociolinguistics of sign languages includes the study of regional and social variation, bilingualism and language contact phenomena, language maintenance and choice, language attitudes, language policy and planning, and discourse analysis (Lucas 1995, 1996, 2001). However, it is very important to understand that while each of these areas has relevance for deaf communities, the sociolinguistics of sign is a relatively young discipline and there exist few if any empirical studies in some of these areas.

1. Regional and Social Variation

Regional and social variation in sign languages has been described mainly at the phonological and lexical levels, and to a lesser extent at the morphological and syntactic levels (see *Dialect and Dialectology*). Variation at the phonological level involves variation in the production of the component parts of signs such as handshape, location, palm orientation, nonmanual signals, and segmental structure. For example, the American Sign Language (ASL) signs FUNNY, BLACK, and CUTE might be produced with the thumb extended or with the thumb closed; the ASL signs BORED and DEAF might be produced with the little finger extended or with the little finger closed; the ASL sign WEEK might be produced with the palm of the dominant hand facing upward or the palm facing downward; the ASL sign KNOW might be produced

on the forehead or on the cheek. Lexical variation concerns different signs for the same concept. Regional differences have been described in British Sign Language (BSL), for example, between Reading and York for the signs LEARN, SUNDAY, and WHO (Deuchar 1984: 131). Lexical variation in BSL has also been described by Kyle and Woll (1985). Lexical variation has also been looked at in New Zealand Sign Language, Italian Sign Language, Dutch Sign Language, Swiss German Sign Language and Swiss French Sign Language, Brazilian Sign Language, and ASL. Variation in terms of ethnicity has been looked at by Woodward (1976) and Aramburo (1989), i.e., differences between black and white signers in the USA. Gender variation has been looked at in ASL, in Chinese Sign Language, and in Irish Sign Language. One large-scale study of sociolinguistic variation in American Sign Language similar to the ones undertaken for spoken languages (Lucas et al. 2001) demonstrates that variation in sign languages needs to be considered in the light of unique factors such as school language policy and language use in the home.

2. Bilingualism and Language Contact Phenomena

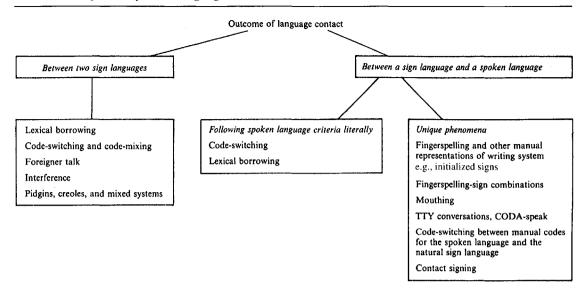
There exist different kinds of bilingualism in deaf communities. For one, most deaf individuals have at least some exposure to the spoken language of the majority community in which they live. This exposure may be primarily exposure to the written form of the majority language, although in many countries a signed code to manually represent the spoken majority language has been devised, with signs invented to represent the bound morphemes of the spoken language. A discussion of bilingualism in deaf communities necessarily requires a re-examination of the term 'bilingual' as it has been used to describe spoken language communities. This is because many deaf people with a firm command of the written version of the majority spoken language choose not to use their voices because they are not able to hear themselves and hence monitor the volume or pitch of their speech. Bilingualism in deaf communities does not necessarily include *speaking* the languages in


Figure 1. Outcome of language contact.

question, at least not in the way that the term *speaking* is generally understood by linguists.

There are many occasions for language contact in deaf communities. Fig. 1 presents a model of the linguistic outcomes of language contact. A fundamental distinction is made between a situation involving contact between two sign languages and a situation involving contact between a sign language and a spoken language, a distinction necessary because of the difference in modality between sign and spoken languages. Naturally, the situation is not entirely straightforward, as two sign languages may be in contact, both of which may incorporate outcomes of contact with their respective spoken languages, outcomes which may then play a role in the contact between the two sign languages.

As can be seen from Fig. 1, the outcomes of contact between two sign languages parallel the outcomes that have been described for contact between spoken languages, namely lexical borrowing of various kinds, code-switching and code-mixing, foreigner talk, interference, pidgins and creoles, and mixed systems. Again, it should be remembered that while there is much anecdotal evidence for many of these outcomes, there are not many empirical studies of the outcomes of contact between two sign languages. Signers borrow the signs from one language into their own; bilinguals may code-switch and code-mix elements from two sign languages; a signer may alter his signing and simplify it when signing to a nonnative, and signers may show interference from one sign language when using another. Signers have been observed to have 'accents.' As concerns contact between a sign language

and a spoken language, a distinction is made between outcomes which reflect literal adherence to the spoken language criteria defined for those outcomes. For example, code-switching would mean ceasing signing and beginning to talk. This is distinct from unique phenomena that occur, such as contact signing, as observed in the American deaf community: the simultaneous production of ASL lexical forms in English word order with mouthing of English words, with the possible inclusion of inflected ASL verbs and ASL nonmanual signals. Some analyses have characterized this as a pidgin but more recent analyses find the features of this kind of signing to be inconsistent with the features of pidgins (Lucas and Valli 1992). Fingerspelling is also a unique phenomenon, because although the forms are part of the natural sign language—i.e., the handshape, the location, orientation, and the segmental structure—it is a representation of the writing system of the majority spoken language. Signers in contact with languages which use the Roman alphabet fingerspell, but signers in contact with Arabic, Russian, Japanese, Vietnamese, and Chinese also represent the writing systems of their respective spoken languages. Other unique phenomena include the English sometimes produced by the children of deaf adults (CODA-speak, Jacobs 1992), and the English of typed telephone conversations that often incorporates features of ASL (Mather 1991).

3. Language Maintenance and Choice

Typically, the use of natural sign languages has been restricted to a very limited set of functions and has

been totally excluded from the educational process. Such a sociolinguistic situation has led to the characterization of language use in the deaf community as diglossic, the majority spoken language being the H variety and the natural sign language being the L variety (Stokoe 1969). There is a lot of evidence that some signers clearly see their natural sign language as appropriate only for intimate, informal situations, and the signed version of the majority spoken language as appropriate for public, formal situations, be the interlocutors hearing or deaf. However, as many countries around the world begin to use natural sign languages in deaf education, these sign languages are acquiring functions that they have not had before, and the spoken or signed version of the majority spoken languages may lose functions they once had or be restricted to the functions of reading and writing. Because of the clear need in deaf communities for both a natural sign language and for some form of the majority spoken language, the situation in most deaf communities can be characterized as one of maintained bilingualism. Unlike many minority languages in a majority language situation, it would not appear that natural sign languages are in any danger of disappearing.

4. Language Attitudes

Language attitude studies in deaf communities concern signers' attitudes toward their natural sign language and toward the majority spoken language, attitudes toward users of the sign and spoken language, attitudes of teachers of the deaf and professionals toward natural sign languages, attitudes toward the invention and introduction of new signs, and attitudes toward the outcomes of language contact (Kannapell 1989). Language attitude studies often reveal conflicting attitudes toward the natural sign language and the majority spoken language in a given community, as a result of lack of recognition of the status of the sign language as a viable and autonomous linguistic system. That is, pride with respect to the sign language may co-occur with an attitude that its use reveals a lower educational level or even lower intelligence in the user, while use of a signed version of the majority spoken language may be viewed as evidence of good education and superior intelligence. Pride with respect to the natural sign language may coexist with the misconception that it is not a real language or is a deficient form of the spoken majority language.

5. Language Policy and Planning

Language planning has been defined as deliberate decision making in response to language problems. Deaf communities have very often been perceived as the sites of language *problems*, particularly as concerns the education of deaf children, for the obvious reason that deaf children do not have easy access to the spoken majority language as a medium of instruction (Ramsey 1997). Approaches since the 1970s have involved the invention of manual codes to represent the majority spoken language and may involve the simultaneous production of the spoken language and the sign language, referred to as sign-supported speech (Johnson et al. 1989). However, many deaf communities around the world are beginning to use the natural sign language of the community as the medium of instruction. All of these approaches have implications for language planning, either in the invention of manual codes for educational use, or in the use of the natural sign language for functions it has not previously had. This may entail expanding the lexicon of the natural sign language, an expansion which leads to other language planning issues, such as whether signs should be invented for new concepts or whether new concepts should be represented with fingerspelling. Issues of access and hence of language policy and planning are not limited to deaf education. For example, providing deaf adults with full access to the business of the majority language community—i.e., media, government, the law, medical care—entails decisions as to how linguistic access will be provided: whether closed-captioning is preferable for television news to a sign language interpreter; whether a sign language interpreter, if provided, should use the natural sign language or a signed version of the spoken majority language; what the interpreting policy should be in an international gathering of deaf people—the natural sign language of the location of the gathering or an international variety or both. These are all issues that are the subject of debate in many deaf communities around the world.

6. Discourse Analysis

As with spoken languages, the discourse of natural sign languages is structured and subject to sociolinguistic description (see *Pragmatics and Sociolinguistics*). Signers use natural sign languages and choices between natural sign languages and other kinds of signing make statements about who they are, what their group loyalties are, how they perceive their relationship to their interlocutors, and what kind of speech event they consider themselves to be involved in. Sign languages are used to establish or reinforce social relations and to control the behavior of others. Sign language discourse has internal structure and is governed by norms such as how many people sign at once, how much one person should sign, what can be signed about in public, how a conversation should be entered or left, how turns should be allocated, how repairs should be undertaken, and so forth (Metzger 1999, 2000, Winston 1999). Topic and the world knowledge that individuals bring to the discourse may also structure it (Roy 1989), and sign language discourse can be described in terms of register

variation (Lawson 1981, Deuchar 1984, Zimmer 1989). The concept of 'language as skilled work' is applicable to sign languages, as skill is demonstrated both in everyday use of language and in special forms such as storytelling and poetry.

Sociology of Language

W. S. Bainbridge

Sociology can contribute to linguistics in four main ways. First, a subdiscipline often called the 'sociology of language' applies sociological techniques of research and explanatory theories directly to

language topics. Second, language appears as a variable in numerous sociological research studies, and considerable factual material of interest to linguistics can be culled from them. Third, several major theories of society place such great stress upon language that they can justly be called 'linguistic theories.' And, fourth, techniques of sociological research have undergone considerable development in the second half of the twentieth century, and many of them can be transferred to linguistics. In return, linguistics can certainly give sociology a greater awareness of the importance and subtlety of language studies. Indeed, sociologists in several subfields seem largely unaware that their work is essentially linguistic, and they could benefit from the rigor and depth of knowledge that professionals in linguistics achieve. Many articles in this *Encyclopedia* have been written specifically to identify the connections between linguistics and sociology, with the hope that these two related scholarly disciplines will cooperate more fully in future.

1. Sociological Studies of Language

Sociologically oriented linguistics, whether called 'sociolinguistics' or the 'sociology of language,' coalesced in the 1960s, although studies of the relation between society and language go back many decades earlier. Dell Hymes dates its emergence in the years 1964 through 1972, explaining that many different factors combined to produce a new interdisciplinary academic field. Writing from the vantage of 1984, Hymes saw the current period as one of transition and consolidation, but transition to what remains unclear. While many scholars now acknowledge the importance of social factors in shaping language, a specific paradigm identifying key questions and establishing correct methods of research for attacking them has not appeared.

In 1972, Hymes introduced the first issue of the important journal *Language in Society* by suggesting that any general theory of language as part of social life and productive empirical research on the topic needed to start with a definition of the field comparable to the following: sociolinguistics is the study of 'the means of speech in human communities, and their meanings to those who use them.' These means and meanings are the forms of speech and their social functions, respectively. Hymes has repeatedly argued that these important questions have been given far less attention than they deserved, greatly because the dominant paradigm within linguistics is the analysis of the formal structure of language, divorced from its social context, as exemplified by the work of Chomsky.

As Joshua Fishman has noted, the difference between sociology of language and sociolinguistics

may be one of mere degree, because both are concerned with the correlation between variations in language usage and variations in other socially patterned behavior. In principle, sociolinguistics takes its agenda from linguistics, and the sociology of language takes its from sociology, the latter stressing the social variables. Fishman (1985: 114) suggests: 'Sociolinguists have continued to be far more often trained in linguistics than in sociology, the latter often being considered useful only for informal exposure and orientation rather than as a substantive and formal body of technical skills and theoretical propositions.'

An important example is the great body of research on social class differences in language. While sociolinguists without number have documented class-related variation in speech, hardly any of them asked themselves what social class was. They treated class as a key independent variable, with variations in speech dependent upon class variations, yet they never considered the meaning of their independent variable. In consequence, they seldom attempted anything like a theory of why class should have an impact, and even more rarely examined their measures of class to see if they were methodologically defensible.

As Michael Macy explains in the essay on social class (see *Social Class*), there is little agreement on the meaning of the term. Sociologists differ on whether society is divided into distinct classes of whether one should speak instead of continuous variation along a number of poorly correlated measures of social influence and status. Competing definitions of class stress ownership of property, control over productive forces, occupational prestige, educational attainment, and many other statuses and resources that confer power and respect upon some members of society. Surely, sociolinguists cannot be expected to solve the difficulties that beset stratification theory in sociology, but before they can employ social class concepts they must become informed about the alternative definitions, explicitly select one that fits their research questions and intellectual leanings, and employ empirical indicators appropriate to their conceptualization. Macy's essay is a good beginning for linguists who want to take this social variable seriously, and every other important sociological concept deserves similarly close study before inclusion in language studies.

Sociology, perhaps more than any other science, emphasizes abstract theory. The central journals are primarily dedicated to empirical studies, but these invariably are attempts to test theories, and purely descriptive research is considered to be of little value. This situation stands in extreme contrast to anthropology, which still believes that documenting the way of life of the peoples of the world is valuable in itself,

as well as for whatever light the data can shed on theories. Because much sociolinguistics strikes sociologists as atheoretical, they consider it unimportant, and perhaps for this reason the central sociological journals hardly ever publish articles whose topic is language.

Thus, if sociolinguists are to be taken to task for failing to give sociology its proper respect, sociologists have returned the insult by ignoring linguistics. One reason may be the ignorance of languages by American sociologists, in a time when America dominated sociology worldwide. When students applied for admission to graduate studies in sociology at Harvard in 1970, the regulations demanded proficiency in two languages beyond English, but by 1971 no foreign languages were required at all. Indeed, the climate in most of the major American sociology departments has strongly discouraged students from studying languages, and some of the programs demand so many courses in quantitative methods and substantive fields of sociology that no time is left over for language study, especially with the great financial and social pressures exerted on the students to complete their degrees quickly. Considering the poor quality of writing by many American sociologists, it may be an exaggeration to say that they are monolingual.

Yet language studies have been officially recognized as a subfield within sociology. A section of the standard reference periodical, *Sociological Abstracts*, is devoted to language, and at least two specialty journals can be said to cover the sociology of language: *Language in Society* and *The International Journal of the Sociology of Language*. However, despite its name the latter of these does not look much like a social science journal, and the former is as close to social psychology as it is to sociology.

Several special issues of *The International Journal of the Sociology of Language* have been devoted to particular languages (Welsh, Dutch, Frisian, Jewish languages) and the language situations of several nations (Australia, Ireland, India, Belgium, and the former Yugoslavia). Few sociologists would recognize these essays as sociological, however, because they are almost without exception wholly descriptive, with no hint of explanatory theory. Like the standard sociology journals, *Language in Society* introduces each article with an abstract, while *The International Journal of the Sociology of Language* does not have them. It is difficult to write an abstract for an essay that consists of a collection of descriptive details, while the abstracts in scientific journals can efficiently state the intellectual problem the research sought to solve, give a brief outline of dataset and methodology, and conclude with a sentence or two reporting how the theory fared in its encounter with the data.

2. Ordinary Sociological Research in Which Language Plays a Key Role

Strewn throughout the vast library of published sociological research is a tremendous amount of information about language usage in various communities and subgroups of the population. Unfortunately for the linguist, no catalogs exist explaining where to find particular data, and nothing short of an intensive literature review will reveal the fruitful sources of linguistic data.

2.1 Studies of Subcultures

Within each large society exist numerous subcultures and countercultures, limited groups of people who share a set of perceptions and behaviors, usually communicating with each other by somewhat unique language. In anthropological parlance, the term 'a culture' has the unfortunate effect of implying the existence of a completely distinct and coherent set of beliefs and customs. Yet individuals within any group of people vary, and every society is a bewildering overlay of innumerable, overlapping subcultures. Ideally, 'subsociety' should be distinguished from 'subculture,' the former referring to a somewhat distinct set of people, and the latter to a somewhat coherent set of cultural elements. Often the two correspond, as when a group of Gypsies remains distinct from the surrounding society, both socially and linguistically. But in many cases, individuals participate in several subcultures simultaneously, while not sharing the same set of subcultural memberships as the fellow members of any particular one.

Consider Tom, Dick, and Harry, three participants in the subculture of illegal drug users. Tom is a computer programmer, Dick a politician, and Harry a burglar by profession. The trio may employ subcultural language while discussing drugs, but when the conversation turns to their work, each lacks appreciation of the argot of the others' professional subcultures, and they are forced to use the common language of their society. Because each subculture has special interests, activities, and artifacts, it will develop a somewhat special lexicon. Countercultures are direct challenges to the dominant culture of their society, and thus they often intentionally invent alternatives for ordinary terminology.

Criminologists have occasionally created dictionaries of the subcultures they were studying. Edwin Sutherland's book about a professional thief contains a glossary defining terms from thief argot, such as *booster* 'shoplifter,' *moll-buzzer* 'someone who steals from the pockets of women,' and *glim-dropper* 'a con man who uses an artificial eye as part of his racket.' A dictionary of inmate terminology was included in Rose Giallombardo's study of a women's prison

where same-sex marriages were contracted between *studs* 'husbands' and *femmes* 'wives,' while those who refused to participate in this subculture were called *squares*.

The sociology of religion records key terminology of new religious movements, often providing etymologies and sufficient information to understand the social mechanisms that generate terminology of various kinds. The sociology of religion roughly distinguishes two varieties of new religious movements: sects and cults. 'Sects' are schismatic movements that arise within standard religious traditions. Typically populated by persons suffering relative deprivation, such as the poor and members of oppressed groups, sects tend to emphasize the otherworldly and revolutionary aspects of the standard religious tradition of the society, but despite their social radicalism they tend to be culturally conservative. Therefore, they do not generate much new terminology, although they not infrequently assign somewhat new meanings to ordinary words.

In contrast, 'cults' are culturally novel or exotic, either arising through processes of radical cultural innovation or being imported from alien societies. Thus, they tend to be rife with neologisms and words adapted from foreign languages. Whereas many cult groups are founded quite independently of any pre-existing religious organization, individual founders of cults almost universally served apprenticeships in other cults. At the moment of its birth, therefore, a new cult tends to be a whirlwind of cultural innovation, but it often draws upon the lexicons of the earlier cults to which the founder had belonged. Like sects, cults are capable of schism, but social rifts in a cult are far more likely to generate new language, because cults are by definition dedicated to cultural innovation.

Literary and artistic schools may also be conceptualized as subcultures, and many have been studied by sociologists. For example, science fiction literature has been produced for more than 60 years by a tight-knit subculture of *fen* 'fans' (*fan/fen* by analogy with *man/men*) and *pros* 'professionals,' with its own extensive lexicon (Bainbridge 1986). H. G. Wells had called his early fiction *science-fantasy*, but when Hugo Gernsback published the first magazine entirely devoted to this kind of literature, he called it *scientifiction* 'scientific fiction.' Gernsback lost financial control of this magazine, founded a rival to it in 1929, and felt forced to coin a new term, coming up with *science-fiction*. The hyphen was gradually dropped by the subculture, to give *science fiction*, which is used in many languages beyond English. The hyphen reappeared in the 1950s when Forrest J. Ackerman coined the slang synonym, *sci-fi*, by analogy with *hi-fi* 'high fidelity sound recordings.' While the literature is often called *sci-fi* by persons outside the subculture, insiders abhor this term, preferring *SF*. While few of the thousands of neologisms invented by science fiction writers have found their way into ordinary parlance, sociology and linguistics can combine in research on how this subculture generates the vast lexicon it does, and a particularly refined minor field is the study of invented languages in literature.

The sociology of slang (see *Slang: Sociology*) has not only documented various brands of substandard speech, but it has identified particular environments that are unusually productive of this level of usage, especially cosmopolitan, urban centers. Indeed, the very term 'slang' may not be capable of definition in strictly linguistic terms, but must be defined sociologically, perhaps as the urban part of popular speech. Among its social functions is the generation of new terminology that may find its way into standard speech. In principle, all subcultural language is a marker not only of social distinctions but of conflict, and slang gives voice to groups and sentiments that currently lack social power.

2.2 Major Social Categories

As mentioned earlier, sociologists have concentrated much effort on understanding social class, and other social divisions have been examined with nearly equal energy, including ethnic groups, professions and occupations, rural and urban populations, and immigrants. The study of sexism and sex differences has been exceedingly fruitful, and sociologists have placed great stress on the role that language may play in sustaining or diminishing power differentials based on gender.

The voluminous sociological research on youth has provided much information on adolescent peer group language (see *Adolescent Peer Group Language*), and young people create and sustain rapidly changing linguistic subcultures that can be studied to understand how new language of potentially any kind is coined and gains acceptance. Youth need special words and symbols to conceal their activities from adults, to provide a sense of group solidarity, and probably to sustain a feeling of leading the vanguard of cultural developments. Youth often seem to feel that they have dreams and experiences previously unknown to the human race, and whether this perception is correct or illusory, it can stimulate the proliferation of neologisms.

Sociology can contribute little to the lexicography of scientific nomenclature and technological nomenclature, simply because scientists and engineers are so active in compiling dictionaries of their own fields. However, many sociologists have investigated both the origins of systems of scientific terminology and the consequences for science of nomenclature that may implicitly assume certain unproven theories are true. Sociological research on technology has often focused on how inventions and terminology spread

95

from one site or application to another, what is generally termed 'diffusion.' Thus, sociology has elucidated the processes through which scientific and technological language emerge and through which they may influence the thought of scientists and engineers.

2.3 Surveys

The vast library of attitude and opinion surveys that can be found in social science computing centers and special repositories, as well as in published reports, contains much largely unappreciated information about language. This is true because many kinds of question ask respondents to say what some stimulus concept means. Often, secondary analysis of archived datasets can extract more information somewhat indirectly by examining the correlations between items; if two concepts are responded to in very much the same way, they must have similar meaning to respondents. Furthermore, surveys have been administered to many different groups of people, and most surveys contain questions that allow the researcher to distinguish subgroups of respondents, thus permitting one to chart variations in meaning across social categories.

The range of linguistically relevant data is immense, so two examples must suffice. In 1924, Bogardus introduced the 'social distance scale,' a question format that asks respondents to say how close they feel to particular kinds of people, such as Germans, Russians, Italians, Caucasians, Asians, Baptists, and Communists. Responses from a number of people allow one to map the concepts and identify groups of them that share substantial overlap in meaning. In the 1950s, Charles Osgood developed a technique, called the 'semantic differential,' that employed statistical analysis of questionnaire items based on antonyms, to chart the affective meaning of concepts. While such techniques can be very useful to linguists planning future surveys, the point worth stressing here is that the data already collected through such methods may now be reexamined profitably from a specifically linguistic perspective.

3. Language-oriented Sociological Theories

At a first approximation, the major theories of society and social interaction may be divided into two classes: idealist and materialist. The latter, including sociobiology, behaviorism, utilitarianism, and Marxism, have little to say about language, with the notable exception of the Marxian concept of false consciousness. However, the idealist theories are based on assumptions about language, give language the dominant role in shaping human behavior, and frequently prompt research with clear implications for linguistics.

3.1 Elements of Social and Cultural Structures

For decades, the most influential sociological theories in the United States were symbolic interactionism and structural functionalism, often combined. The first emphasizes the way language shapes the individual, for example, through development of verbally coded self-symbols called 'personal identity,' 'self,' or 'role.' The second emphasizes the shared concepts of the society, such as institutions, values, norms, and generalized beliefs. In linguistics, there is much talk about the 'deep structure' of language, but sociological concepts like 'role' and 'value' refer to the 'deep content.' In its structuralist guise, structural functionalism analyzed the relationships between elements of the culture (e.g., between roles and institutions), thus placing these elements into a comprehensive conceptual structure where they were mutually dependent.

For decades, practically every introductory sociology textbook has explained to students that every society is based on a coherent set of values which constitute the goals individuals and groups are supposed to strive for and which provide the necessary cultural basis for social stability. Supposedly, societies differ greatly in their value systems, and an historical change of values will have a profound effect on a society. While linguistic in nature and communicated through speech, values are of such a general nature that they dwell implicitly in all messages rather than being stated explicitly in a few words, except in special public occasions such as religious sermons and political speeches.

However, research has generally failed to find very solid support for these sweeping hypotheses about values, and a host of alternative perspectives has arisen since the 1950s that place far less credence in values and portray society as far less coherent and far more conflictual. For instance, exchange theory, exemplified by the antisociological sociology of George Caspar Homans, holds that humans act so as to maximize individual gain, guided by past personal experience more than by abstract values communicated through language.

The distinctively sociological brand of social psychology known as 'symbolic interactionism' continues to give language great importance, especially in creation of potent abstractions such as self and the variety of behavior-orienting concepts associated with role theory. Research on attitudes and behavior has shown that words and deeds often diverge, good reason to doubt that words have the distinctive power to shape human action and social organization that earlier generations of sociologists assumed. But this merely limits the presumed power of values and roles; it does not automatically render them impotent.

Under social conditions that researchers are increasingly able to specify, words can have great

power over the individual mind and collective behavior. Most importantly, to the extent that a set of people are united by social bonds into a cohesive group, clearly bounded from other groups and sharing a unique fate, then a coherent set of values, norms, roles, and self-conceptions is likely to arise. Once such a symbolic system exists, supported by social unity and ideological consensus, it possesses all the potency attributed to culture by earlier generations of sociologists. The only question is the extent to which modern societies have such cohesion.

More or less organized forms of thought and culture are expressed through collective representations and constitute conceptual systems. Traditional religion possesses the coherence and absolutism required to sustain a conceptual system and value orientation, as do some modern totalitarian political parties (Stark and Bainbridge 1985). However, secularization and pluralism appear to undercut the authority of religion considerably, and history in the late twentieth century has shown the impossibility of maintaining totalitarianism without savage, brute force. Thus one must anticipate that the present fluid situation will continue, with values and similar language-based abstractions holding sway only in limited social environments, conceptual systems rising and falling in chaotic manner, thus challenging the social scientist to determine when words possess or lack distinctive power in society.

The branch of sociology that has considered these issues most deeply for the longest period of time is the sociology of knowledge. This subdiscipline is concerned with the ways that material and social factors condition people's beliefs, thought, and general culture. Recognizing that human knowledge is historically bounded, writers in this tradition have considered the role of social change and group conflict in strengthening ideological fixity, as well as in weakening it.

3.2 Social Conflict: Language as Battleground

Acknowledging that words often diverge from deeds, when people say one thing and do another, words can also be deeds of a particularly powerful kind. Through words, people may define social conditions in ways favorable to their own interests, gaining influence over the language of discourse as if it were a battleground contested in a war of words. Sociologists have examined in depth how labels may create reality, and if some of the theories have outstripped the truth, the sociological schools of labeling theory and social constructionism offer much of interest to linguistics.

3.2.1 Labeling Theory

The labeling theory of social deviance, often called 'social reaction theory' or 'societal reaction theory,' contends that much if not most deviance is caused by definitions unnecessarily imposed on individuals and actions by capricious society. As Ronald Akers explains, labeling theory is rooted in symbolic interactionism, the influential sociological perspective that considers each person to be the creation of the symbols he or she has received in communication with other people. Thus, society can create a criminal or a madman by taking an otherwise undistinguished person and applying these negative labels to him. Akers's report that scientific evidence tends to refute some of the more striking statements of labeling theorists does not diminish the fact that this is a thoroughly linguistic theory of crime, mental illness, and other forms of deviance.

Among the creators of labeling theory and the societal reaction perspective was Edwin Lemert, who distinguished two categories of norm violation. 'Primary deviation' has many causes, arising out of a variety of social, cultural, psychological, and physiological factors, and Lemert finds it quite uninteresting. 'Secondary deviation' consists of responses to problems created by societal reaction to primary deviation, and thus it is the result to a very great extent of the labels people attach to behavior they dislike. Among the narrowly linguistic studies published by Lemert from this perspective are two that concerned stuttering among the indigenous people of British Columbia, Polynesia, and Japan. He contended that societies which strenuously attempt to correct stuttering, such as Japan, will have more of it than societies which respond less aggressively to minor speech defects, such as Samoa. The primary deviation represented by mild and occasional stuttering produces more or less harsh reaction from listeners, depending upon the norms of the culture, and harsh reactions will cause greater self-consciousness on the part of the stutterer, thus aggravating the condition and producing much secondary speech deviance.

Another linguistic application appears in the analysis of schizophrenia offered by Thomas Scheff. Contemptuous of psychiatry, Scheff summarizes five decades of research and 5000 publications in just five words: 'no progress has been made.' To fill this void, Scheff offers a labeling theory that considers schizophrenia to be a pattern of secondary deviation caused by reaction to a variety of primary deviation he calls 'residual deviance.' In a thought experiment, Scheff asks us to imagine listing all the kinds of norm violations that exist, and to check off those that have explicit labels in the language of the society, words like 'crime, perversion, drunkenness, and bad manners.' He then says, 'After exhausting these categories, however, there is always a residue of the most diverse kinds of violations, for which the culture provides no explicit label.' Psychiatric symptoms, according to Scheff, violate norms that are poorly articulated by the culture, and societal reaction to

random violations of this kind can magnify and stabilize them into full-fledged madness. Indeed, being mentally ill is nothing more, for Scheff, than being labeled mad and playing the role of mad person as scripted by the society.

Extreme versions of labeling theory hold that everything is a matter of definition, but it is an objective fact that such definitions often have great importance for public policy. In a study of abortion, homosexuality, and drug addiction, Edwin Schur argued against criminalization of acts which have no victims. He defines victimless crimes as 'the willing exchange, among adults, of strongly demanded but legally proscribed goods or services,' thus implying that no one involved in the exchange has any complaint. A 'victim,' for Schur, is a person who has the legal standing to appear in court and wishes to lodge a complaint. To sustain this definition, he has to argue that an aborted fetus is not a person with legal standing, that society is not harmed by any sexual practices of its members, and that *drug addict* is a misnomer for a person who merely wants to ingest proscribed substances. Schur notes that members of society disagree about all these matters of definition, yet the term 'victimless crime,' widely used by reformers of the 1990s, seeks to define the debates in terms of one particular side to them.

3.2.2 Social Constructionist Perspectives

The phrase, 'social construction of reality,' is extremely popular among sociologists, but is open to very different interpretations. Many take it to mean that reality is socially created, for instance, that the categorization schemes of science are arbitrary choices made entirely on a whim by the social groups who happen to be in charge of scientific institutions. For them, the word *construction* comes from the verb *to construct* and suggests that scientific definitions are built from scratch under purely social influences. Translations of German sociology often render *Aufbau* as *construction* in this sense. An alternative derivation of *construction* is from the verb *to construe*, suggesting that humans merely interpret or explain realities that exist in nature quite apart from the meanings humans attach to them. These can be called the strong and the weak meanings of the social construction of reality.

According to the strong social constructionist view, social problems originate in public opinion and the actions of interest groups, rather than in objective conditions. Armand Mauss (1975) contends that social problems are generated by social movements, and, in a sense, that problems are nothing but movements. A traditional definition of social problem is 'an undesirable social condition,' but this leaves entirely open the question of who has the right to decide what is undesirable. Mauss is able to document the importance of social movements in

defining aspects of many conditions as undesirable: crime, juvenile delinquency, drug abuse, alcohol abuse, prostitution, homosexuality, abortion, racism, pollution of the environment, and the population explosion.

An objective condition is not problematic until it is defined as such. Because crime is violation of law, there are no crimes until there are laws, so crime is caused by legislatures and the social movements that agitate them. Many brain-affecting drugs are consumed in great quantities, including alcohol, tobacco, aspirin, and coffee; such behavior does not become *drug abuse* until activists in the medical profession or politicians define free use of a particular substance as bad, a maneuver that generally succeeds only with substances like marijuana that are consumed primarily by politically weak segments of the population. Sexually explicit literature and pictures only become *pornography* when defined as unwholesome by religious or other movements that are seeking some means of promoting themselves with the public.

The mechanism by which social movements typically produce social problems is the launching of 'symbolic crusades.' These can be defined as collective struggles to promote, resist, or repair symbolizations. In other words, they are attempts made by a more-or-less organized group of people to make the culture accept a particular set of definitions.

A classic example is the Temperance Movement, which emerged in the United States early in the nineteenth century, then spread its doctrine of moderation or abstinence in alcohol use to Europe. Joseph Gusfield argued that this movement was not really about drinking but about intergroup conflict over status, power, and wealth: 'Issues of moral reform are one way through which a cultural group acts to preserve, defend, or enhance the dominance and prestige of its own style of living within the total society' (Gusfield 1963: 3). If it can get its particular set of ideal norms officially accepted by the society, then it will gain respect, prestige, and emulation from other groups.

American cultural groups traditionally differed in their attitudes toward alcohol, Catholics accepting drinking more readily than Protestants, for example. Rural, native-born, Protestants valued self-control, industriousness, and impulse renunciation, according to Gusfield, and uninhibited imbibing was contrary to their culture. Many of the new immigrant groups whose members and political strength grew as the years passed had a more favorable attitude toward drinking. The old citizens and new citizens were frequently at odds over economic issues, but because economic conflict takes a muted form in American politics, symbolic issues like alcohol policy came to have an exaggerated importance. As they felt their political power slipping, the older ethnic groups tried to assert the superiority over other citizens through

advocating laws to promote their own temperate drinking patterns as the dominant norm. If their customs became law, their declining social status would be symbolically bolstered. This analysis has been expanded by Seymour Martin Lipset and Earl Raab (1970) to include a range of conservative symbolic crusades that apparently arose in response to persistent problems of social status experienced by the same ethnic groups.

Like labeling theory, the theory of symbolic crusades exhibits social definitions on two levels. First, it is a theory of how a social movement promotes particular sets of symbols. Second, the social theorists themselves aggressively apply definitions to the social movement under study, almost invariably beginning from a personal rejection of the definitions possessed by the people they are defining. Simply put, the social theorists are of liberal or left-wing political persuasion, and the movements they analyze are conservative or right-wing. In part, the theory of symbolic crusades arose in the attempt to explain why socialist movements had failed to become prominent in the United States. The left-wing sociologists were convinced it was in the workers' interests to support socialism, and yet the American working class has often seemed attracted to the political right. Some invoked the Marxist concept of false consciousness, arguing in effect that the working class had been tricked into accepting the definitions of the ruling class, and the theory of symbolic crusades similarly asserts that members of a movement are deceived or deceiving about the real meaning of their symbols.

Often a distinction is made between 'interest politics' and 'status politics.' When a class supports political parties and movements that promote its economic interests, then it is practicing interest politics. But when it engages in activity counter to, or irrelevant to, its economic interests, in an apparent attempt to gain status through invoking certain cultural symbols, then it is engaging in status politics. Flag-waving by persons who are not members of the ruling class thus becomes understandable as a grab for status through claiming to embody traditional values of the society.

Despite its origins on one side of political debates, the concept of symbolic crusades can be applied more widely. For example, movements to establish or expand civil rights of a subordinate group often recruit many people who are not members of the oppressed, and their participation may be explained in terms of status politics. Most leaders of the movement to abolish slavery were not themselves slaves. In the early 1960s, a substantial proportion of the activists in the American Civil Rights Movement were Northern Whites who believed themselves to be embodying the best traditions of their nation, and thus they were asserting claims to the highest moral status. Clearly, the theory of symbolic crusades has a tendency to debunk the claims of the crusaders, and thus the attractiveness of the theory depends to some extent upon it being applied only to movements with which one does not personally sympathize.

3.3 Social Construction of Languages

Perhaps the most significant symbolic crusades are the attempts to create a sense of shared national identity. As Greenfeld explains in her article on nationalism and language (see *Nationalism and Language*), the conventional view of the relationship between nations and languages is that nationhood rests on a shared language; for example, that Germany is defined as the nation of people who speak German. But an alternate view holds that nations are fictions created symbolically, and among the most effective methods for achieving this is the creation of a national language (see *National Language/Official Language*).

Nations do not exist in the world of nature any more than races do; while human beings vary along a number of dimensions, including habits of tongue and hues of skin, no substantial population has ever been wholly separate from other populations. Thus, the concept of 'nation' is in many respects a creation of the imagination, and Greenfeld charts the rather complex history of this word, arguing that England invented nationalism in the sixteenth century, and that all other nations have adopted the concept from the English. Every student of linguistics is aware that several lesser modern languages have been codified as instruments of nationalism, among them Afrikaans, Hebrew, and Norwegian. But Greenfeld's examples are far more influential and spoken by far vaster populations: English, French, German, and Russian. Arguing that language is not the foundation of nationalism but its product, she firmly establishes the need of linguistics to become rooted in sociology.

In his discussion of colonialism (see *Power Differentials and Language*), Pierre van den Berghe notes that the concept of 'ethnic group' has some of the properties Greenfeld attributes to 'nation.' In principle, an ethnic group is a set of people defined as descended from common ancestors, but such definitions may be partly fictitious. Often, language is the chief marker of ethnicity, in part because endogamy maintains both ethnic and linguistic boundaries. Ethnic groups, and thus their languages, differ in power, and the world has seen many instances in which a colonial power has sought to impose its language upon conquered ethnic groups, from the Classical world of Greece and Rome to the empires of England, France, and Russia. Imperialism establishes the dominance of one ethnic group over others, and thus it is accompanied by linguistic stratification in which the language of the conquerors is defined as

99

better than those of the conquered. Only in extreme circumstances, such as slavery, are the languages of the oppressed annihilated, however, and the decline of colonial empires is almost inevitably followed by the resurgence of the previously dominated languages.

Within modern societies, certain professional groups have sought cultural dominance over others, notably intellectuals and physicians. Kontopoulos (1994) notes the many competing definitions of this term, but for present purposes the fact can be stressed that intellectuals manipulate ideas, including definitions, in order to impose their often oppositional agendas upon the society. They may do this under the guise of professional expertise, but often it is the sheer mental facility with which they organize thought that compels a measure of acceptance.

In a process called 'medicalization,' physicians and their allies redefine phenomena as medical in nature, thus convincing the public to grant them the sole right to manage the phenomena. For example, heavy alcohol drinking has been seen as a personal choice, a character defect, or a sin requiring religious treatment. By analogy, and without clear scientific evidence, doctors redefined heavy drinking as *alcoholism*, a medical syndrome, and thus they gained social power over it. Another example is *hyperactivity* in children. Modern society demands that girls and boys sit quietly in school chairs for many hours each week. Some children, chiefly boys, fail to comply with this demand. Their physical activity is greater than their teachers wish, and the doctors have come to the teachers' rescue by defining the unruly children's behavior as a medical syndrome. Such a definition discredits the children's behavior and thus prevents them from successfully asserting their rights. The hyperactive children are often given drugs to alter their behavior, and the educational system is defended against any hint that it might be founded upon false principles.

4. Linguistic Research Methodologies

While most sociological research uses language, a few important techniques provide such valuable insights into language and are so solidly based on plausible theories of language that they deserve to be mentioned here. At the same time, methodological insights from all branches of sociology will help sociolinguistics improve the accuracy of their results. Especially important issues of research methods concern questions of reliability, validity, bias, sampling, scaling, and understanding of meaning.

4.1 Problems of Reliability and Validity

'Reliability' and 'validity' are two different aspects of the quality of a method of research or source of information. The reliability of a research technique is the consistency of results that it provides. A reliable

questionnaire item tends to get the same response from a respondent if administered twice, so long as the relevant circumstances have not changed. Validity has to do with whether the technique measures what the researcher intends it to. A valid questionnaire item accurately reflects the desired aspect of the respondent's thoughts, behavior, or characteristics. Thus both validity and reliability are problems of measurement, and both need to be achieved to create confidence in the results of research.

An example of invalidity is offered by Calvin Veltman (1986), who severely criticized the two language questions in the Canadian census, one seeking information about what language is used at home and the other asking whether the person can carry on a conversation in one of the two official languages of Canada, French and English. Veltman surveyed hundreds of Greek and Portuguese immigrant households, asking a variety of questions about language use and competence. Answers to the census question about the language used at home revealed that 64 percent of the children of Greek families used Greek exclusively, and 68 percent of the Portuguese children used only Portuguese at home. However, when the same respondents were asked what language they used to speak to family members of different generations, huge discrepancies emerged. When conversing with parents and grandparents, the overwhelming majority spoke the mother tongue, whereas when speaking with siblings and friends, most children spoke French or English. Thus the 'home language' question is an invalid measure of the language habits of young people, and more directly reflects the habits of the older generations.

Veltman is critical of the question about the respondent's capacity to carry on a conversation in an official language, because it is not demanding enough. His own research inquired if respondents speak French or English 'very well' or 'quite well.' This more stringent approach indicates a substantially higher proportion who are effectively monolingual in Greek or Portuguese. Furthermore, Veltman found that the relationships between the questions vary in often unpredictable ways, showing somewhat different patterns among the two groups of immigrants. Whether or not Veltman has found the right way to collect statistics on language usage, his work has cast a dark shadow of suspicion over the validity of the language data from the Canadian census.

4.2 Respondent and Interviewer Bias

An interview is a social interaction, and thus the validity of a respondent's answers may be shaped by the characteristics of the interviewer and of the interview situation itself. A questionnaire is merely an attenuated form of interview, and thus its results also may suffer from biases introduced by the act of collecting the data (Block 1965, Berg 1967).

'Response bias' is the tendency of a respondent to answer questions in a particular way, regardless of what the question specifically is about. A very common bias is 'acquiescence,' the tendency of a respondent to agree with whatever an interviewer or survey says, regardless of its content, or to disagree. A tendency to agree is called *yea-saying*, and a tendency to disagree is called *nay-saying*. The tendency of a respondent to give socially acceptable answers to questions, putting himself in a good light, is called 'social desirability bias.' This form of bias is especially troublesome in linguistic surveys, because the formal setting of the interview may encourage respondents to be more formal than usual in their manner of expression, shifting their speech toward the prestige standard.

These are not new problems. In 1929, Stuart A. Rice discovered 'contagion bias,' the tendency of the data to be infected by the attitudes of the interviewer, either because respondents adjust their answers to fit their impression of what the interviewer wants, or because the interviewer adjusts the answers when writing them down. And in 1942, Daniel Katz examined 'interviewer bias' in a survey of opinions about labor-related and war-related issues, finding significant differences in response depending upon the social class of the interviewer. Similarly, respondents give significantly different patterns of response to interviewers of a different race than to members of their own group. Anderson et al. (1988) found that Black respondents replied differently to questions about race relations, depending on the race of the interviewer. This phenomenon has been discovered independently in linguistics, where it is called 'accommodation,' the tendency of one person to adjust speech style to match that of another (see *Speech Accommodation*).

Howard Schuman, who has vast experience in constructing and administering surveys, prefers to conceptualize these issues in terms of the question–answer process in attitude surveys (see *Attitude Surveys: Question–Answer Process*). Research employing two or more versions of a question has revealed often substantial differences in responses, dependent upon often subtle differences in wording. Apart from alerting linguists to methodological problems that need to be avoided or solved, this body of research has unearthed evidence about language itself. For example, supposed synonyms may get different responses, including synonyms that are the negation of an antonym; for example, 'forbid' turns out to mean something substantially different to respondents than does 'not allow.' Similarly, the effect of the interviewer on responses reminds us that words do not have precise, invariant meanings, but take on meaning depending upon the social situation in which they are uttered.

4.3 Methods of Survey Sampling

While the aim of social research is to arrive at justified conclusions about human populations, there is seldom time or other resources to survey every single member, and resort must be made to sampling. There are many kinds of samples, however, and they differ greatly in their suitability for various kinds of research (Kish 1965). At the extreme, a sample may be so hopelessly biased that it completely ruins research based on it.

A 'convenience sample' is a subset of the population polled simply because they were easy to contact, and highly accessible respondents may often exhibit somewhat different language from less accessible ones; for example, they may be better educated than the average, or belong to particular ethnic groups that are more hospitable to strangers. In a 'snowball sample,' the researcher begins with some individuals who are appropriate informants and then asks them for referrals to other appropriate informants; for example, one might locate Greek speakers in Edinburgh by visiting a Greek restaurant and asking each Greek one meets to give the names and addresses of other Greeks. The danger here is that one may survey one stratum or subgroup in the Greek population, without knowing which one or how the others differ.

A 'purposive sample' consists of a set of cases which the researcher has carefully considered and which in his or her judgment will serve the needs of the research; for instance, school teachers with apparently Greek names could be taken from a list of all school teachers in Edinburgh. A 'quota sample' sets targets for how many people are to be included from each of several categories; one might survey 100 middle-class Greeks and 100 working-class Greeks. This approach allows one to evaluate linguistic differences between the categories, but it has little power to guard against problems caused by divisions in the population other than those explicitly considered by one's quota system.

Perhaps the standard sampling approach is the 'simple random sample,' created using random numbers or other chance-based procedures, selecting individuals from the population at random. Each member of the population has an equal chance of appearing in the sample, and every combination of a given number of individuals also has an equal chance. A 'systematic sample' is a cheap imitation of a random sample, taking perhaps every tenth name from a list; it saves a little time in actually drawing the sample but offers less confidence in the results and has no justification today when computers can quickly draw true random samples. A 'cluster sample' also saves time and money, by drawing a modified random sample in which respondents are clustered together geographically

into groups that can be visited more cheaply than if the individuals were strewn across the landscape.

Often, a combination of quota and random sampling can achieve better results than either approach alone. At the outset, the researcher can identify categories of people in the population, just as in quota sampling, and decide how many of each is needed. For example, in doing a survey in Quebec one might want substantial numbers of both French speakers and English speakers in the final dataset. Then, a random sample is drawn for each of the categories separately, and the result is a 'stratified random sample.' A 'proportionate sample' is a sample that sets quotas for the groups of respondents that match their distribution in the population.

One may sample not only persons from a population but linguistic features from a comprehensive style and language fragments from a larger text. When McIntosh and his colleagues worked with such diligence to produce the *Linguistic Atlas of Late Mediaeval English*, they did not record every instance of every variant of every feature in the 1200 manuscripts they studied. Instead, they worked with samples of text, and the principles of sampling developed for use with questionnaire surveys are readily adapted to sampling any other kind of universe. For example, a 'multistage sample' could be drawn from a corpus of texts by first taking a random sample of texts, say 10 percent of the total, then taking a random sample of lines from the selected texts.

4.4 Multivariate Approaches

Many of the statistical techniques used by social scientists in the late twentieth century are designed to work with several variables simultaneously, and such multivariate techniques will undoubtedly be of ever greater prominence in linguistics. Restricting one's scholarly labors to a single variable is like trying to do dialectology by listening to only one word. In the Bible, it proved possible to distinguish Gileadites from Ephramites by attention to how they pronounced the initial sound in *shibboleth*, but modern scholarship would want to combine many pieces of information. Generally, two justifications are given for the multivariate approach. First, a combination of variables is probably more reliable and precise than any single measure, in part because a single variable is apt to contain a considerable amount of random variation or noise. Second, it is possible to measure a general concept by combining data about a number of its aspects; for example, information about wealth, education, and community power may be combined to measure social class.

Roughly speaking, there are two ways to combine many variables into a composite measure, the synthetic and the analytic. In order to measure a general concept with precision, several variables are blended into a new, synthetic variable, called a scale or index. Or, there can be at the outset a large number of variables that presumably measure different concepts, and use techniques of statistical analysis to divide them into groups, each of which reflects a particular concept.

In his article on scaling (see *Scaling*), Earl Babbie notes a variety of ways to combine variables to make a composite scale. Perhaps the simplest is to add together a set of separate variables, giving each one an equal weight. For example, late Middle English manuscripts can be distinguished in terms of whether they were Northern or Southern, and a particular manuscript could be described by counting what percentage of a list of linguistic features were Northern. Often, however, there is good reason to believe that the individual measures are not equal, some being more powerful than others, or some kinds of measures being more numerous than others, and there is a need to weight the variables in some way before combining them. For example, if dialects were to be distinguished both phonetically and lexically, and there was somewhat more information about the written form of words than their pronunciation, then each particular lexical variable might be given less weight, so that in total they equaled the weight of the data on pronunciation.

Factor analysis is one of a number of widely used techniques for arranging a number of variables along a set of dimensions, and once this is done the variables clustered along one dimension can be combined into a reliable scale. An example relevant to language is a study of the ideologies of science fiction literature (Bainbridge 1986). Nearly 600 participants at a world science fiction convention rated their preferences among 73 well-known authors, and a computer calculated the 2628 correlations linking pairs of authors, under the assumption that highly correlated authors in the preference ratings must share important stylistic and ideological qualities. A factor analysis then discovered four dimensions of variation, essentially dividing most of the authors into four groups, purely on the basis of the statistical data from respondents. One group was simply classic writers, such as Jules Verne and H. G. Wells. The other three dimensions were clearly different kinds of modern literature, and it was possible to correlate them with other items in the questionnaire to identify each one in terms of the underlying messages it conveyed.

The statistical analysis revealed that 'Hard-Science' authors based their fiction on the physical sciences and new technology, extrapolating what might be the next steps taken in particular sciences, and their stories were very similar to factual science articles and reports on the space program. Their protagonists were unemotional and intelligent, and the reader could expect a rational explanation for

everything that happened. In contrast, 'New Wave' writers wrote avantgarde fiction that experimented with new styles and was based on the social sciences. Their fiction deeply probed personal relationships and feelings, often concerned harmful effects of scientific progress or was critical of society, and included a considerable body of feminist literature. The 'Fantasy Cluster' of authors and styles included several subtypes of literature, including myths, legends, sagas, epics, 'sword-and-sorcery,' ghost stories, and tales of horror. Based on magic rather than science, and having affinities with art and poetry, it concerned alien cultures, strange characters, and protagonists who were brave and aggressive. This study sought high-level, abstract messages communicated by dozens of authors in hundreds of publications, but factor analysis can be applied to analysis of meanings and linguistic forms in many different kinds of data.

William Rau believes that multidimensional scaling will find greater applications in linguistics than factor analysis (see *Statistics in Sociolinguistics*), because it is suited to a wider range of data. The first step in factor analysis is the calculation of a matrix of correlation coefficients, and this requires that the variables meet certain mathematical criteria that may not often be met by language data. In demonstrating how multidimensional scaling can be applied to three different kinds of linguistic data, Rau explains that students of language may want to employ these techniques in a very different way from that typically used by sociologists. Both factor analysis and multidimensional scaling can discover the structure either of the variables or of the cases, depending on how these techniques are applied. Sociologists usually want to learn how the variables relate to each other, while linguists may want to understand relationships among cases. That is, the student of language may want to analyze speech differences across regions of a nation or individual persons within a community, and Rau convincingly demonstrates how this can be done profitably for linguistic scholars.

4.5 Content Analysis

Any systematic approach that seeks to measure the patterns of meaning communicated through existing samples of language can be called 'content analysis.' Many research traditions in sociology and numerous specific studies have developed coding schemes or other techniques for extracting meaning from utterances. A classic example is the Kuhn and McPartland twenty-statements test (Kuhn–McPartland 1954). In the original version, a respondent was asked to write 20 statements beginning with the words 'I am.' The researcher would then assign each statement to one of two main categories, *consensual* and *subconsensual*. The consensual responses 'refer to groups and classes whose limits and conditions of membership are matters of common knowledge.' Examples given included: student, girl, husband, Baptist, from Chicago, premed, daughter, oldest child. In contrast, the subconsensual responses 'require interpretation by the respondent to be precise or to place him relative to other people.' Examples were: happy, bored, pretty good student, too heavy, good wife, interesting.

During the 1980s, researchers have tended to use a slightly different coding scheme in which the first category is social, those responses that identify the person in terms of social roles or membership in social groups. A second category is psychological, responses that describe a mood or mental attitude. It has been suggested that the proportion of responses in each category varies from decade to decade, or from one group of respondents to another, some being more oriented toward other persons, and some more oriented toward the self. Such a coding scheme can readily be applied to naturally occurring speech or written text, as well as to text generated in response to the researcher's instructions.

As Kathleen Carley points out in her article on content analysis, a classic approach, exemplified by the General Inquirer computer system, was to count the number of times each word appeared in a sample of text, with the assumption that the more often something was mentioned the more central it was to the meanings being communicated. In the 1980s and early 1990s, techniques have been developed for examining the connections between words or concepts, indeed for determining the meaning of a term in the ways respondents associate it with other words. Another technique, which has been applied to the problem of determining the authorship of texts, is the analysis of values or other high-level meanings contained in texts (Rokeach et al. 1970). Clearly, coding schemes for categorizing naturally occurring speech are tools of linguistics, even though most of them have been developed by sociologists and psychologists.

4.6 Qualitative Approaches

Although the methodology of quantitative research has progressed rapidly, sociologists have not abandoned qualitative methods, especially those designed to extract meaning from human actions and speech. In particular, the classic work of Max Weber continues to be influential. Weberians argue that one cannot understand the action of an individual unless one appreciates what the elements of the situation mean to that individual, and the process of seeing things from the perspective of the person is given the technical name '*Verstehen*', from the German verb 'to understand.' Weberian analysis is often conducted through the creation of 'ideal types,' abstract formulations that identify categories of

meaning to which phenomena may be assigned, yet which preserve their qualitative distinctiveness and the subjective meanings that may be assigned to them. This approach has influenced the development of ethnomethodology (see *Ethnomethodology*), which in turn has encouraged analysis of conversation in linguistics. Ideal-typical analysis has generally been applied to widely shared cultural phenomena, such as Protestantism, but it also dovetails with much work done in social psychology.

5. Disorganization and Reorganization

A union of sociology and linguistics could not lead to the conquest of one by the other, if for no other reason than that sociology is highly fragmented, rife with factional battles and schools of thought that have nothing to say to each other. At various times, attempts were made to unify sociology around one or another set of theoretical or methodological principles, and all were failures. One reason is the great diversity of phenomena that sociologists study; only a fanatic would assert that one theory was capable of explaining family life, crime, urbanism, modernization, religion, industrial relations, and sex roles. Another is the ideological burden that sociology sadly bears; a substantial portion of those recruited to the ranks of sociologists are already committed to one or another reform movement, a fine thing for social progress but an impediment to objective analysis and to development of really scientific social science. Still another reason is the practical and moral difficulty in testing social theories conclusively, which means that practically every idea ever proposed remains plausible to at least some school of thought; the relative merits of opposing positions can seldom be determined objectively, and the intellectual pruning required for progress seldom takes place.

Still, the wealth of ideas, information, and insights possessed by sociology is immense, much of it valuable for language scholars. Sociologists in many fields study language, and many would profit from the realization that they are practicing amateur linguistics and from the professional training that would elevate the level of their work. The resurgence of sociology outside the United States, in nations where knowledge of several languages is the hallmark of an educated person, bodes well for the future of the sociology of language. The extreme disorganization of sociology has set the stage for at least partial reorganization, and the fact that language is the central phenomenon for many subdisciplines and perspectives suggests that a reorientation of sociology toward linguistics could achieve a new paradigm for the study of human social life.

Speech Community

B. B. Kachru

The terms 'speech community' and 'linguistic community' are widely used by linguists and other social scientists to identify communities on the basis of their languages (e.g., Swahili speech community, English speech community, linguistic communities of India). In linguistic descriptions and analyses, these terms are used to make descriptive and theoretical generalizations. However, speech community, like another often-used term, 'dialect,' cannot be defined rigorously. True, all users of a language seem to know what speech community (or communities) they belong to, or not belong to. This intuitive affiliation with a given speech community is not different from the lay-person's notion of a dialect, and dialect identification.

1. Toward a Definition

The definitions range from Bloomfield's (1933: 42) rather broad conceptualization of 'a group of people who interact by means of speech,' to the very complex characterization by Bolinger (1975: 333):

> There is no limit to the ways in which human beings league themselves together for self-identification, security, gain, amusement, worship, or any of the other purposes that are held in common; consequently there is no limit to the number and variety of speech communities that are to be found in society.

Hymes (1974: 47–51) considers a speech community 'a social rather than linguistic entity.' Such a community shares 'knowledge of rules for the conduct and interpretation of speech' (see *Hymes, Dell Hathaway*).

Firth's (1959: 208) distinction between 'a close *speech fellowship* and a wider *speech community* in what may be called a language community comprising both written and spoken forms of the general language' is very useful (see *Firth, J. R.*). The fellowships are based on the social, caste, religious, geographical, and professional identities one desires to establish. A restricted definition, that members of a speech community usually inhabit the same area and speak the same variety or standard of a language, is misleading.

2. Characteristics of Speech Communities

In characterizing a speech community, one must note several features. First, a speech community crosses political boundaries: for example, English cuts across the political boundaries of Canada, the USA, Australia, and New Zealand. In South Asia, the Bengali speech community is divided between Bangladesh and India, the Tamil-speaking speech community between Sri Lanka and India. In Africa, the Swahili speech community is spread over Kenya, Tanzania, Uganda, and Democratic Republic of Congo. Arabic is used as the first or an additional language in several states in the Arab world and in parts of Africa and Asia.

Second, a speech community does not necessarily represent one religion or culture. Bengali, for example, is spoken by two separate religious groups within two distinct cultural contexts in Bangladesh, and in the state of West Bengal in India.

Third, speech communities comprise idiolects and dialects. An idiolect is the total speech repertoire of a single person, and a dialect marks a person's membership in a particular group (see *Dialect and Dialectology*).

3. Types of Speech Communities

Speech communities are classified into four major types on the basis of their linguistic composition (see Ferguson 1996, Kachru 1997).

3.1 Multilingual

A 'multilingual' community officially recognizes more than two languages. In South Asia, India provides a paradigm example of such a community, recognizing 15 national languages out of the estimated 1652 or more languages and dialects used in the country. In Africa, Nigeria recognizes four official languages: English, Hausa, Igbo, Yoruba. In East Asia, Singapore has four official languages: Chinese, English, Malay, Tamil. In Europe, Switzerland recognizes three official languages: German, French, and Italian. The recognition of linguistic pluralism does not mean that in terms of functional range, and societal depth of use all the recognized

105

languages have identical status and currency. In India, for example, for pan-Indian and international functions, the 'associate' official language, English, has greater currency. Hindi, the 'official' language, has wider uses than the regional languages such as Bengali and Tamil. In Singapore, Tamil has fewer functions than has Chinese, Malay, or English. A country may officially declare itself multilingual, but in reality its constituent states may be essentially monolingual. In Switzerland, for example, in Geneva, Zurich, and Ticino, the majority of the population use only French, German, and Italian, respectively (Kloss 1967).

A multilingual country generally adopts a contact language, often with an official status. During the Austro–Hungarian monarchy, German served this purpose in parts of Austria until 1918. In India, Hindi–Hindustani performs this function, as did Russian in what was until 1991 the USSR.

3.2 Bilingual

A 'bilingual' community has two languages with an official status. In Botswana, Tswana and English are official languages. In Cameroon, French and English have this status. In Canada, English and French have official status. In Finland, Finnish and Swedish, and in Sri Lanka, originally Sinhalese and Tamil were two official languages. When Sinhalese was made the sole official language, the result was years of unrest, violence, and open demands for secession by the Tamil minority.

Among bilingual speech communities, there is a difference between, for example, Belgium and Canada, where two languages are recognized but the two constituent units are essentially monolingual, as opposed to Singapore and India where bilingualism/multilingualism is part of the linguistic behavior and linguistic repertoire of most individuals.

3.3 Diglossia

Originally, 'diglossic' community (*di* 'two,' *glossia* 'languages') was used in the specific sense of two varieties of one language which are functionally complementary. The earliest use of the term, 'diglossie,' was probably by Krumbacher (1902) to show the relationship between the two varieties of Greek, the written and the oral. Ferguson (1959) used the term to refer to:

> ... a relatively stable language situation in which, in addition to the primary dialects of the language (which may include a standard or regional standards), there is a very divergent, highly codified (often grammatically more complex) superposed variety...

In a diglossic situation, there are two varieties of a language, High (H) and Low (L). The H variety is generally used in formal contexts (see *Diglossia*).

There are many diglossic communities. Arabic-speaking communities make a distinction between Classical and colloquial varieties of the language. Among Greek-speaking communities this distinction has been applied to the H variety, termed Katharévousa and the L variety, termed Dhimotiki (Demotic). In this case of Tamil, a Dravidian language spoken primarily in Tamil Nadu state of India and in parts of Sri Lanka, a distinction has traditionally been made between literary and classical varieties. In Telugu, spoken in Andhra Pradesh state of India, two distinct varieties, 'granthikā' (literary; H variety) and 'vyavhārikā' (colloquial; L variety) are used. In Bangladesh and India, Bengali makes a distinction between 'sādhu bhāṣā' (cultivated speech; H variety) and čolit bhāṣā (colloquial speech; L variety). In Switzerland, the German-speaking parts have a H variety of German ('Hochdeutsch,' the standard) and an L variety termed 'Schwyzertüütsch,' which includes a range of regional dialects of Swiss. In a diglossic context, the L variety is acquired as a child while the H variety is generally acquired later. There has been considerable discussion of diglossic communities and the implications of diglossia for education and allocation of linguistic power. Diglossia has also been used for what actually are bilingual situations: one community using two languages, e.g., the use of Spanish and English by the Puerto Ricans in New York. There has also been an attempt to shift away from the earlier use of this term by Ferguson, particularly in the work of Gumperz (1964), Fishman (1967), and Hymes (1974; see also Hudson 1980).

Among diglossic communities distinction must be made between, for example, the situation of the Arabic-speaking populations and Haiti. Haiti is considered a diglossic community where children first learn Haitian Creole and later, when they enter school, learn French. In Arab countries, the Arabic-speaking children learn the formal variety of Arabic in school.

3.4 Monolingual

A 'monolingual' community essentially recognizes one language, as in Japan, Korea, Malta, and Portugal. However, the term is a misnomer, since monolinguals have a verbal repertoire which includes various dialects, styles, and registers. Switches in styles and registers often entail special efforts in learning and education. In earlier literature, the USA and the UK were perceived as monolingual speech communities but this perception was actually based on an attitude and not on the facts.

4. Speech Community and Linguistic Repertoire

The members of a speech community command a 'linguistic repertoire,' 'code repertoire,' or 'verbal repertoire.' The terms, used more or less

interchangeably, refer to the total range of languages, dialects, styles, and registers available to a member of a speech community for interaction with other members. A multilingual country may recognize such a repertoire in the educational system, as India, for example, recognizes the 'Three Language Formula.' The formula, proposed in the 1960s, requires study of three languages in school: English, Hindi, and the regional language. In the Hindi areas (Central India) students are required to study a Dravidian language (Kannada, Malayalam, Tamil, or Telugu) to balance what is termed the 'language load.'

In the case of monolinguals, such a repertoire may entail dialect, style, and register shift. The use of a particular code out of the total repertoire may also mark a hierarchy of contexts or shift in linguistic identities and functions (Kachru 1982).

5. Speech Community, Language Rivalry, and Conflicts

Speech communities are rarely harmonious. They manifest various types of rivalries and conflicts. In postcolonial Africa and Asia the issues primarily relate to language standardization, e.g., the development of terminology to equip languages for modern scientific and technological demands, for administration and education, for developing and stabilizing registers and for providing writing systems or simplification of graphemic systems. The conflict may be motivated by seeking recognition for a language or a dialect not recognized in the language policy, e.g., demands of the Rajasthani, Maithili, and Urdu speakers in India (Kachru and Bhatia 1978). Such conflicts may result from attitudinal readjustment toward a language or its varieties, e.g., the demands for recognition by the minority language speakers in the UK and India, and by the speakers of Black English in the USA. The underlying motivations for such rivalry and conflicts are to establish language identity (Heller 1987).

In multilingual speech communities, interaction in many languages and dialects may result in development of new codes of communication (see *Code-switching: Overview*).

6. Conclusion

In conceptualizing a speech community one may either emphasize the shared linguistic rules, or the societal and functional factors. The institutionalized languages of wider communication used across languages and cultures (e.g., English) have raised many interesting theoretical and descriptive issues concerning terms such as 'speech community' (Kachru 1988, 1996).

SECTION II
Language and Interaction

Antilanguage
P. A. Chilton

'Antilanguage' is a term used by the British linguist M. A. K. Halliday to refer to the variety of a language spoken by an 'antisociety,' that is by such social subcultures as criminals, immigrant and other disadvantaged communities, as well as marginal groups such as students, conscripts, and prisoners. Such subcultures, according to Halliday, stand in a 'metaphorical' relationship to the main society: they are a part of that society, but are peripheral or antagonistic to it. This ambivalent relationship is represented in the 'antilanguage' characteristic of such groups. Examples are the language of the criminal underworld in Elizabethan England ('pelting'), the Bengali underworld variety of twentieth-century Calcutta, and 'grypserka,' the antilanguage found in Polish prisons in the 1970s. The function of antilanguages is in part to maintain secrecy, but also to symbolize the symbiotic relationship between society and antisociety. The linguistic characteristics of antilanguages include metathesis, syllable addition, transposition of syllables (as in 'pig-Latin' and French 'verlan'), and transposition of consonants:

e.g., in the Bengali antilanguage of Calcutta, *kodān* ('shop') derives from standard Bengali *dokān*. Many lexical items of the standard language are replaced and multiplied by grammatical expansion and metaphorical or metonymic substitution: e.g., Elizabethan pelting *darkmans* ('night'), *Rome-booze* ('wine'). On the phonological, grammatical, and semantic levels, therefore, antilanguages can be said to create alternative meanings and alternative realities, which are mirror images of the standard language and society.

Audience Design
A. Bell

Audience Design is a theory of language style (see *Style*). Proposed in Bell (1984), who derived the term from Clark (Clark and Carlson, 1982), it has become the most widespread approach to style in sociolinguistics (Eckert and Rickford, 2001). Audience Design proposes that speakers' style choices are primarily a response to their audience.

The framework has been summarized (Bell, 1997) under nine headings:

(a) Style is what an individual speaker does with a language in relation to other people. Style is essentially interactive and social, marking interpersonal and intergroup relations.

(b) Style derives its meaning from the association of linguistic features with particular social groups. The social evaluation of a group is transferred to the linguistic features associated with that group. Styles carry social meanings through their derivation from the language of particular groups.

(c) The core of Audience Design is that speakers design their style primarily for, and in response

109

to, their audience. Audience Design is generally manifested in a speaker shifting their style to be more like that of the person they are talking to—'convergence' in terms of Speech Accommodation Theory.

(d) Audience Design applies to all codes and levels of a language repertoire, monolingual, and multilingual.

(e) Variation on the style dimension within the speech of a single speaker derives from and echoes the variation, which exists between speakers on the 'social' dimension. This axiom claims that quantitative style differences are normally less than differences between social groups.

(f) Speakers show a fine-grained ability to design their style for a range of different addressees, and to a lessening degree for other audience members such as auditors and overhearers.

(g) Style shifts according to topic or setting derive their meaning and direction of shift from the underlying association of topics or settings with typical audience members.

(h) As well as the 'responsive' dimension of style, there is the 'initiative' dimension where a style shift itself initiates a change in the situation rather than resulting from such a change. Sociolinguists have drawn attention to this distinction at least since Blom and Gumperz's proposal of situational versus metaphorical styles (1972). In responsive style shift, there is a regular association between language and social situation. Initiative style trades on such associations, infusing the flavor of one setting into a different context, in what Bakhtin (see *Bakhtin, Mikhail M.*) has called 'stylization' (1981). Language becomes an independent variable which itself shapes the situation.

(i) Initiative style shifts are in essence 'referee design,' by which the linguistic features associated with a group can be used to express affiliation with that group. They focus on an absent reference group rather than the present audience. This typically occurs in the performance of a language or variety other than one's own (see Rampton's (1995) concept of Crossing; *Ethnicity and the Crossing of Boundaries*).

Audience Design has been contested on a variety of grounds—the priority it gives to social variation over style, disregard of the role of attention to speech, and in particular inadequate attention to the active, constitutive role of language in interaction.

Later developments in Audience Design (e.g., Bell, 2001) have countered by stressing the proactive nature of language style in identity formation and presentation. Responsive and initiative style are treated as different but concurrent dimensions of language usage, manifesting the structure/agency duality familiar in social theory. This accords both with the stress in contemporary social theory on language as constitutive, and with the dialogical theory of Bakhtin (1981). The range of linguistic analysis in Audience Design has also been increasingly extended to include qualitative and co-occurrence analyses as well as quantification.

Conversation Analysis

P. Drew

Research in conversation analysis (hereafter CA) has paralleled the development within sociolinguistics, pragmatics, discourse analysis, and other fields in linguistics, toward a naturalistic observation-based science of actual verbal behavior. Recordings of naturally occurring conversations are analyzed in

order to discover how participants understand and respond to one another in their turns at talk, and how therefore *sequences* of activities are generated. Conversation Analysis is thereby a bridge between linguistic analysis (especially pragmatics) and the sociological investigation of sociality, conversation being a primary medium of interaction in the social world, and the medium through which children are socialized into the linguistic and social conventions of a society. The main objective of CA is to uncover the sociolinguistic competences which underlie the production and interpretation of talk in social interaction. While the principal focus of CA is 'ordinary conversation,' its perspective and methods are also applied to interaction in institutional settings such as classrooms, medical consultations, courts, psychiatric therapy sessions, news interviews, and the workplace.

1. The Origins of Conversation Analysis

The most immediate origin of CA is the period during 1963–64 which Harvey Sacks (see *Sacks, Harvey*) (1935–75) spent at the Center for the Scientific Study of Suicide in Los Angeles. Drawn by his interests both in the ethnomethodological concern with members' methods of practical reasoning and commonsense understandings (arising from his association with Garfinkel), and also in interaction (somewhat stimulated by his having been taught by Goffman (see *Goffman, Erving*) while a graduate student at Berkeley), Sacks began to analyze telephone calls made to the Suicide Prevention Center (see Schegloff 1989; see *Schegloff, Emanuel*). Without any diminished sensitivity to the plight of persons calling the SPC, Sacks investigated how callers' accounts of their troubles were produced in the course of, and were designed to be fitted into, their interactions with the SPC staff member with whom they were talking. This led him to explore the more generic 'machinery' of conversational turn-taking, and of the sequential patterns or structures associated with the management of activities in conversation. Through the collection of a larger corpus of more mundane telephone calls, and through his collaboration with Jefferson and Schegloff, that exploratory work has been considerably refined and developed, so that now there is quite a comprehensive picture of the conversational organization of turn exchange; overlapping talk; repair; topic initiation and closing; sequences initiated by such activities as greetings, questions, invitations, and requests; agreement/disagreement; story telling; discourse markers (such as 'well' and 'oh'); laughter; non- or quasi-lexical response tokens; and of the integration of speech with nonvocal activities. Conversation Analysis research reveals how such technical aspects of talk are the structured, socially organized

resources whereby participants perform and coordinate activities through talking together.

2. Data and Transcription

The primary data for CA are recordings of naturally occurring interactions, detailed transcriptions of which enable researchers to search through episodes in many different conversations (with varying content, different participants and different contexts) with the aim of identifying stable systematic phenomena, and collecting multiple instances of those phenomena. The following extract from the recording of a telephone call is representative of the transcribed data used in CA research.

```
[NB: II: 2: 17–18]
 1  Emma:   Wanna c'm do:wn 'av a bah:ta lu:nch with me?=
 2          = Ah gut s'm beer'n stu:ff,
 3          (0.3)
 4  Nancy:  Wul yer ril sweet hon; uh:m
 5          (.)
 6  Emma:   ⌈ Or d'you 'av sump'n ⌈ else(  )
 7  Nancy:  ⌊ Let-  I:     hu   ⌊ n:No: I haf to: uh call Roul's
 8          mother, h I told'er I: 'd call 'er this morning
 9          I ⌈ gotta letter from 'er en .hhhhhh A:nd uhm
10  Emma:     ⌊ (Uh huh.)
11          (1.0)
12  Nancy:  .tch u-So: she in the letter she said if you ca:n why
13          (.) yihknow call me Saturday morning en I i'st haven't
14          h ⌈ .hhhh
15  Emma:     ⌊ Mm hm:=
16  Nancy:  =T's like takin a beating. (0.2) kh ⌈ hh hnhh hnh hnh
17  Emma:                                       ⌊ M m::: . No one
18          heard a wo:rd hah.
19  Nancy:  Not a word.
```

A transcript such as this does not replace the original audio/video recording from which it was made: the recording and transcript are analyzed in conjunction with one another. The transcription system employed (developed by Jefferson; see Atkinson and Heritage 1984: ix–xvi) is, like all transcription systems, necessarily selective: it does not, for instance, represent aspects of sound production in as much detail, or as systematically, as might a phonetic transcription. However, it does enable many essential characteristics of speech delivery to be conveyed, including some morphological and phonetic alternations, lexical choice, speech perturbation, and aspects of prosody including stress and sound lengthening. CA transcripts capture especially well those aspects of talk which are believed to be interactionally salient, and which other transcription systems often fail to notice and record. Particular care is taken to represent accurately features associated with the sequential development of talk, notably the transition from one speaker to the next, including the exact placement of overlap onset, and pauses. CA

111

transcripts of recorded conversations display the actual verbal behavior of speakers, in just the way it happened, including the kind of syntactic and other disfluencies which Chomsky regarded as the corrupt details of linguistic performance, and which consequently have been widely ignored in linguistic analyses of hypothetical and idealized versions of 'well-formed' sentences.

Such disfluencies as *self-repair* are evident in the above extract, for instance in line 7 where the speaker cuts off the beginning of her turn, and twice restarts it; and again in line 12, when after 'So: she' the syntax of her utterance is interrupted by inserting the phrase 'in the letter,' before then resuming with 'she said....' Self-repair is quite methodically related to interactional concerns (e.g., speaking in overlap; constructing an account or story), and hence part of speakers' interactional competences (Schegloff, et al. 1977, Goodwin 1981). Aspects of talk such as those captured in the above transcript could not be recovered by making field notes, by precoded schedules, or by recollection. Through the repeated re-examination of data which CA transcripts make possible, analysts are able to investigate and uncover the organization of many aspects of verbal behavior in interaction, including the kind of disfluencies illustrated (self-repairs associated with turn restarts, and insertions) which have previously been dismissed as the nonstandard products of randomizing factors, and therefore not subject to linguistic or social organization. However, CA transcripts are undoubtedly not complete, and other compatible interactional organizations may be revealed by closer transcription of some phonetic detail (Couper-Kuhlen and Selting 1996, Kelly and Local 1989).

CA has typically relied on the analysis of tape-recorded telephone calls, thereby controlling out nonvocal behaviors (e.g., bodily movement, gaze, gestures) which may be related to talk in face-to-face interactions. Nevertheless, its perspective and methodology are perfectly applicable to the investigation of the systematic relationships between verbal and nonvocal conduct (Goodwin 1981, Atkinson and Heritage 1984, Peraklya 1995).

3. The Sequential Context of Turns-at-Talk

The fundamental objective of CA research is to explicate the ways in which, during the turn-by-turn progression of conversation, coparticipants make sense of one another's talk, and how they design their own turns at talk so as to be appropriate next moves. Thus the sequential patterns which analysis uncovers are the emergent products of participants' understsandings of what each other said in a prior turn, and their response to that in their 'next turn.' From a participant's perspective, conversation is a collaborative activity, in which one turn/move progressively leads to a next on the basis of an analysis/understanding (i.e., participant's analysis) of that prior turn. CA aims to capture that progressivity in the production of successive turns at talk, by explicating the procedures whereby (a) the transfer of speakership from one participant to the next is organized, such that speakers take turns, and (b) the analysis/understanding which each makes of the other's prior turn/action is displayed in the design or construction of their next turn.

A central property of conversation appears to be that it is organized into single speaker turns, with regular transitions between speakers. Participants take turns at talk, with one party at a time occupying a turn, then a next, and so on. The transition from one to the next is coordinated so as to achieve minimal gap (i.e., pauses) and minimal overlap. The procedures or techniques for managing smooth transitions from one speaker to a next are general enough to take into account such local contextual variations as the identities and number of speakers, length of turns, content, setting, etc. Sacks et al. (1974) formulated a set of rules for turn-taking which are context free (i.e., allow for such local variations), but which are applicable to the local circumstances of particular turns in particular conversations. These rules, in which either current speaker selects next speaker, or if current speaker has not done so then another may self-select, operate at each point where a turn could be treated as 'meaningfully' and recognizably complete, i.e., at the end of each 'turn construction unit' (TCU), the end of such a unit being a turn transition relevance point.

Participants' orientation to the completion of a construction unit as a point where speaker transition may legitimately occur is evident in some of the detail in the transcript above. For example, at the end of line 1, where a unit of talk (an invitation) is recognizably complete, and therefore at just the point where recipient might begin speaking, Emma 'rushes through' (indicated by the 'equals' symbol) to add an inducement to accepting her invitation:

1 Emma: Wanna c'm do:wn 'av a bah:ta lu:nch w ith
        me? =
2   = Ah gut s'm beer'n stu:ff.

Hence speaker latches on a next TCU before recipient has the opportunity to self-select and begin speaking on completion of the TCU/invitation in line 1.

An orientation to the completion of a TCU and hence the legitimate relevance of turn transition is manifest in the occurrence of *overlap* (Sacks et al. 1974, Jefferson 1986, Schegloff 2000). In line 6 of the data extract, Emma starts to speak, happening thereby to start simultaneously with Nancy who continues (line 7) her response to Emma's invitation: they thereby talk (briefly) in overlap. Although apparently a violation of the 'one speaker at a time'

expectation, the onset of overlap is orderly insofar as Emma begins speaking at a point where Nancy has produced a complete TCU ('Wul yer ril sweet hon:'), and which is therefore a transition relevance point. Nancy also orients to the 'one speaker at a time' expectation, by cutting off her turn in line 7 until the end of Emma's turn in line 6 is projected. The onset of overlapping talk is overwhelmingly located at or very close to the completion of a TCU, and hence at the projected end of current speaker's turn (even if it should turn out, as here, that current speaker continues). Thus overlap in conversation is the orderly product of those procedures for managing smooth transfer from one speaker to the next.

When a next speaker takes a turn at talk, he/she displays in the design of that turn an understanding or analysis of the prior speakers' turn. That is, following speaker A's 'initial' turn, speaker B's next turn will be designed to be fitted with or be an appropriate response to speaker A's prior turn: hence B's next turn will exhibit his/her understanding of what A just said/did. So for example, Emma's turn in line 6 of the above extract displays her understanding of Nancy's prior turn in line 4:

```
4  Nancy:   Wul yer ril sweet hon: uh:m
5           (.)
6  Emma:    Or d'you 'av sump'n    else (  )
```

It is evident in line 6 that Emma treats Nancy's prior turn as implying that she has a difficulty accepting Emma's invitation, i.e., that she may have 'something else' to do.

Because participants' analyses of each other's talk are manifest in their responses or next turns, adjacent or 'next turn' is a basic structural position in conversation. To begin with, it is the slot in which, if B discerns something amiss or incorrect in A's prior turn, then B may initiate *repair* in his/her next turn. Furthermore, insofar as the meaning which B attributes to A's prior turn is exhibited in an adjacent next turn, speaker A may inspect B's response to discover whether B properly understood, i.e., to check the adequacy or correctness of B's understanding. If A finds B's understanding to be wanting or in error, then A may in his/her next turn (in effect, the third position in a sequence) initiate repair in order to correct B's misunderstanding. In either respect, next or adjacent turn is the primary position for establishing mutual comprehension and for the initiation of repair in conversation. It is the slot in which adequate understanding is displayed, confirmed, or remedied: it is, therefore, the major location and resource for establishing and continuously updating 'intersubjective understandings' in talk-in-interaction (Schegloff 1992).

A turn's construction, therefore, involves speaker selecting a relevant or appropriate next action in response to the perceived action in a coparticipant's prior turn: in other words, a turn is constructed with respect to its placement in a sequence of actions. However, a further aspect of turn construction or design should be emphasized, that of 'recipient design.' The descriptive terms which speakers select are contextually sensitive: they take into account not only the topic of conversation, but also contextual circumstances relevant to the talk (see *Context*). These circumstances may include relative states of knowledge; for instance, in reference to persons, speakers select between alternative forms of reference, and particularly between those forms premised on recipient knowing the person to whom reference is made, and those which assume recipient does not know that person. An illustration is provided in the data extract, when in lines 7–8 Nancy refers to 'Roul's mother....' The selection of a proper name assumes that her recipient, Emma, will recognize that the person so named is her exhusband Roul: but by referring to his 'mother' instead of naming her, Nancy orients to any difficulty Emma might have in knowing/recognizing whom she has to telephone that morning were she to refer to her by name. Hence speakers' descriptions of persons—involving the selection between proper names and other identifications (here, a relational term, 'mother')—are so designed as to take into account recipient's relative knowledge about the persons thus described. Thus in the recipient design of her descriptions, speaker orients to relevant features of the *context* of the conversation, and in particular what coparticipants know about one another and their circumstances (evident also in Emma's implied reference in lines 17–18 to what she knows about Nancy's troubled relationship with her exhusband).

4. Adjacency Pair and Preference Organization

The extract above further illustrates one of the central concepts in CA research, that of 'adjacency pair,' which links the apparatus for turn transfer and next speaker selection, with the production of the next turn in an action sequence. When in line 1 Emma asks if Nancy would like to come down and have a bite of lunch, she makes an invitation. In her response in line 4, Nancy embarks on what Emma plainly believes to be the beginning of a possible rejection of that invitation. An invitation, followed by its acceptance/rejection, is one of the class of paired actions known as adjacency pairs.

Many kinds of current turns at talk sequentially implicate a range of possible responses on the part of recipient: e.g., if current speaker announces some form of trouble or bad news (see Nancy's idiomatic reference to 'trouble' in line 16 above), then recipient might be expected to respond by sympathizing, or enquiring further about the speaker's trouble (as Emma does in lines 17–18). But for a certain class of initial actions, such as questions, greetings,

113

invitations, requests, accusations, offers, etc., that expectation applies in a particularly 'strong' and circumscribed fashion. The production of one of these initial actions projects and requires that in his/her adjacent next turn recipient should produce a quite specific second, complementary action. For example, if speaker asks a question, the appropriate response by recipient is expected to be an answer: or if speaker makes an invitation, recipient is expected to respond by accepting or declining it. Similarly accusations are paired with defences, a greeting with a return greeting, requests with grantings/rejections, and offers with acceptances/rejections.

Hence the production of the first part of an adjacency pair, e.g., an invitation, sets up a constraint that the speaker thus selected should follow directly by producing the second part in the relevant pair i.e., an acceptance/refusal. This constraint might appear to be violated in cases where one first pair part is met by next speaker producing another first pair part, as when a request, such as *Can I borrow the car?* gets the response *How long do you need it?* However, in responding that way recipient can be heard to ask a question which is a preliminary to dealing with the request, that is checking out information which recipient may need in order to decide whether or not to grant the request. Thus recipient's question initiates an 'insertion sequence,' on the completion of which (as when first speaker replies *Just until lunchtime*) a response to the request (i.e., a granting/rejection) is still 'conditionally relevant.' The conditional relevance of an appropriate response to the first part of an adjacency pair does not refer to a statistical generalization about the adjacent sequencing of actions: instead it highlights the 'normative' character of the constraint or expectation that next speaker should produce an action which is the second part of a pair initiated by a prior speaker's asking a question, making an invitation, etc. Participants' orientation to the normative character of adjacency pairs is evident, for example, in the accounts which may be provided when a response to a first pair-part is not forthcoming from recipient—accounts which may range from the possibility that recipient did not hear, through to the recognition that recipient disagrees with some premise or position taken in the initial action (so if a speaker has taken a position in a question, and there is no immediate response from recipient, speaker may infer from that that recipient disagrees: speaker may therefore reformulate the question to modify the position to bring it in line with what is now assumed to be recipient's position. (See below on agreement and disagreement.)

Whereas the initial actions in some adjacency pairs relevantly get only one type of response, for instance questions get just answers, some other adjacency pairs listed above allow for alternative actions to be done as responses to the initial actions, e.g., invitations may get either acceptances or rejections, and requests may be granted or rejected. These alternative second pair parts are not equivalent. Broadly speaking, there is a bias towards those next/second actions which promote social solidarity and which avoid conflict (Heritage 1984: 265–80). That is, there is a 'preference organization' associated with the selection of acceptances and rejections (e.g., of invitations), in which acceptances are preferred actions, and rejections are dispreferred actions. 'Preference' here does not refer to any personal psychological or motivational dispositions of individual speakers. It refers instead to the finding in CA research that these alternative actions are routinely performed in systematically distinctive ways. Briefly, preferred actions such as acceptances are normally produced unhesitatingly, without delay, are delivered right at the start of the response turn, are packaged in short turns, and are unmitigated. In contrast, when a dispreferred response such as a rejection is delivered, the turn-start is often delayed (e.g., by a pause), and the dispreferred action itself further delayed by being prefaced by other components, including such brief objects as 'uh,' 'well,' and 'I'm not sure,' and in some cases by 'positive' forms (e.g., token agreements, appreciations). Dispreferred actions are normally produced in variously mitigated or attenuated forms: and they are often accompanied by accounts, explanations, and the like.

Some of these features associated with dispreferred responses help to account for how in line 6 of the above extract Emma anticipates that Nancy may be going to reject her invitation (i.e., these are features which are oriented to by participants in understanding one another). Nancy's response is first delayed by the 0.3 sec. pause in line 3; it is then preceded by 'Well' (line 4), one of those components which both further delays the response, and expresses some reservation. The rest of her response in that line consists of an [appreciation] component,'.... yer ril sweet ho̲n: uh:m,' a 'positive' form which often prefaces and mitigates an upcoming rejection, as in *Well that's awfully sweet of you, I don't think I can make it this morning. hh uhm I'm running an ad in the paper and–and uh I have to stay near the phone* (Atkinson and Drew 1979: 58). This rejection of an invitation is preceded by an [appreciation]; the [rejection] component is mitigated (in 'I don't think I can make it,' rather than 'I can't make it'); and is then accompanied by an [account] for her inability (rather than unwillingness) to come this morning (note that Nancy's account in line 7 is similarly formed as a constraint or inability, 'I ha̲f to: uh ca̲ll...'). Emma treats Nancy's production of the [appreciation] here as premonitoring rejection, and offers on Nancy's behalf an account for not being able to accept, 'or d'you ' a̲v sump'n e̲lse.' In this way

first speaker's activities (here, Emma's) can collaboratively contribute to the avoidance of explicit versions of dispreferred actions, and hence to the maintenance of social solidarity.

The general point is, therefore, that 'preference organization' refers to certain systematic differences in the design of alternative but nonequivalent responses, in terms of their sequential properties (notably delay of dispreferred actions) and the designs of the turns in which preferred and dispreferred actions are produced. This applies also to the organization of 'repair/correction' in conversation (see Schegloff, et al. 1977 on the preference for self-repair over other repair); and most notably to 'agreement' and 'disagreement' in conversation. Research shows that a speaker's agreement with prior speaker is expressed directly and without delay (often just overlapping the turn with which agreement is being expressed), and in an explicit unmitigated form, often by repeating some form used by prior speaker (see Nancy's confirmation of what Emma proposed, lines 17–19 above) or by upgrading the prior speakers' assessment. By contrast, disagreements are often delayed sequentially, by pauses or by a series of prior turns; they are frequently delayed by being prefaced with agreement components; and when they are stated, their expression is often mitigated or 'weakened' (Atkinson and Drew 1979, Heritage 1984, Levinson 1983, Pomerantz 1984). In all these and other respects, there are formal social or institutionalized procedures which work to maximize agreement and other affiliative actions, and minimize disagreement and disaffiliative actions. These formal procedures reside in the details of the sequential management of preferred and dispreferred actions, and in the details of the design of the turns in which they are performed.

5. Topics of CA Research, and Connections with Linguistics

This review of the central importance of 'next position' as the locus for displaying understanding, and some aspects of adjacency pairs and associated preference organization, serves to highlight the interdependence in CA research of the investigation of sequential management of actions in conversation, and the way in which the performance of an action shapes the design of the turns in which they are performed. While CA's concern with turn design is focused principally at the level of lexical choice, together with certain non- or quasi-lexical verbal objects, the organizations or patterns which have been identified at that level are likely to be consistent with other levels of linguistic organization, e.g., phonological variations (Kelly and Local 1989, on phonological aspects of turn holding versus turn transfer). On this and other issues concerning the interactional salience of prosodic features, and

studies of how next speakers' responses are systematically related to prosodic variations, see Couper-Kuhlen and Selting 1996. But the distinctive contribution of CA has been to identify and explicate the patterns manifest in the interrelationship between action sequences and turn design: and to have demonstrated that participants themselves, in their contributions to the turn-by-turn development of conversation, orient (though not necessarily consciously) to those very organizations, patterns, or systematic procedures.

The sequential patterns identified through CA research are, in very real ways, bound up with the interactional enterprises which engage participants in conversation. Among such patterns are those associated with presequences (enquiries which are preliminaries to making invitations or requests, designed to check the likely success of such actions); troubles tellings; repair initiation, and particularly the avoidance of explicit correction of one's coparticipant; the elicitation and display of affiliation through laughter; telling stories; the initiation and closing of topics, and the more imperceptible 'stepwise' transitions from one topic to another; performing delicate actions 'off the record' or unofficially; and greetings, complaint, request, and invitation sequences.

Topics such as these are intrinsically relevant to those perspectives in linguistics which are concerned with language use in interaction. But CA research has a further and quite direct contribution to make to a range of areas in linguistics, including the analysis of (indirect) speech acts (CA has shown that speech activities are understood by participants contextually, by reference to the placement of turns within sequences of actions); the pragmatics of description (the relation between lexical selection and sequential environment, recipient design, and self-repair are all relevant); discourse markers (studies have shown that markers such as 'well,' 'anyway,' 'oh,' etc. perform specific sequential and interactional functions); syntax (the relationships between syntactic constructions and the management of turn transfer); prosody and phonetic organization (e.g., again, related to turn transfer); and discourse cohesion (for a review of CA's contribution to understanding the relation between conversational and linguistic structures, see Levinson (1983), and for what CA can contribute to our understanding of grammar 'at work' in interaction, see Ochs et al. 1996).

Finally, it should be noted that although CA has developed through and has its primary focus in ordinary conversation, it is more properly a perspective for analyzing 'talk-in-interaction,' including adult–child interaction, and talk in workplace and institutional environments. Research into the latter, especially those settings in which talk is subject to specialized speech exchange systems and restricted participation rights (especially involving question–answer exchanges), is

beginning to identify distinctive sequential patterns associated with the particular interactional purposes and goals which participants have in institutional contexts (Atkinson and Drew 1979, Drew and Heritage 1992, Drew and Sorjonen 1997).

Conversational Maxims

J. Thomas

H. P. Grice had worked with the philosopher J. L. Austin at Oxford in the 1940s and 1950s. Grice's work on the cooperative principle (CP) (see *Cooperative Principle*) and its related conversational maxims arises from the same tradition of ordinary language philosophy. In his book *How to Do Things with Words* (1962; 2nd edn. 1976), Austin made the distinction between what speakers say and what they mean. Grice's theory tries to explain how a hearer might get from the level of expressed meaning to the level of implied meaning.

It is perhaps easiest to begin with a concrete example of the type of problem which Grice's theory was designed to handle. On a visit to London, two friends returned to their parked car to find that it had been wheel-clamped by the police. The driver turned to his passenger and said: *Great, that's just what I wanted!* It would doubtless have been clear to the passenger, as it would have been to any competent interactant, that what the driver intended to imply was very different (just the opposite, in fact) from what he actually said. Grice set out to explain the mechanisms by which such implicatures are generated and interpreted.

Grice first outlined his theory in the William James lectures, delivered at Harvard University in 1967 (a version of which was published in 1975 in his paper 'Logic and Conversation'), and expanded upon it in papers published in 1978 and 1981. Grice never fully developed his theory—there are many gaps and several inconsistencies in his writings. Yet it is this work—sketchy, in many ways problematical, and frequently misunderstood—which has proved to be one of the most influential theories in the development of pragmatics (see *Pragmatics and Sociolinguistics*).

1. The Four Conversational Maxims

Grice (1975) proposed the four maxims of 'quantity,' 'quality,' 'relation,' and manner,' which were formulated as follows (1):

Quantity: Make your contribution as informative (1) as is required (for the current purpose of the exchange).
Do not make your contribution more informative than is required.

Quality: Do not say what you believe to be false.
Do not say that for which you lack adequate evidence.

Relation: Be relevant.

Manner: Avoid obscurity of expression.
Avoid ambiguity.
Be Brief (avoid unnecessary prolixity).
Be orderly.

A speaker might observe all the maxims as in the following example (2)

Father: Where are the children? (2)
Mother: They're either in the garden or in the playroom, I'm not sure which.

The mother has answered clearly (manner), truthfully (quality), has given just the right amount of information (quantity), and has directly addressed her husband's goal in asking the question (relation). She has said precisely what she meant, no more and no less, and has generated no implicature (that is, there is no distinction to be made here between what she says and what she means).

Grice was well aware, however, that there are very many occasions when people fail to observe the maxims (this might be because, for example, they are incapable of speaking clearly, or because they deliberately choose to lie). In his writings, he discussed each of these possibilities, but the situations which chiefly interested him were those in which a speaker *blatantly* fails to observe a maxim, not with any intention of deceiving or misleading, but because the speaker wishes to prompt the hearer to look for a meaning which is different from, or in addition to, the expressed meaning. This additional meaning he called 'conversational implicature,' and he termed the process by which it is generated 'flouting a maxim.'

2. Flouting a Maxim

A 'flout' occurs when a speaker *blatantly* fails to observe a maxim at the level of what is said, with the deliberate intention of generating an implicature. There follow examples of flouts of each of the maxims in turn, and also a review of Grice's discussions of the reasons for flouting a maxim.

2.1 Flouts Necessitated by a 'Clash between Maxims'

A speaker flouts the maxim of quantity by blatantly giving either more or less information than the situation demands. For example, imagine someone asked a departmental colleague who was standing next to the clock if he would tell them the time. Imagine he replied: *Well, according to this clock it's a quarter to four*, when he could simply have said: *It's a quarter to four*. According to Grice, such a response would set in motion a process of informal reasoning which would lead one to derive and additional piece of information. This might work in the following way (3):

(a) Your colleague has clearly given you more (3) information than you required. He appears to have breached the maxim of quantity.

(b) However, you have no reason to believe that he is being deliberately uncooperative (i.e., that he is failing to observe the cooperative principle (CP)).

(c) You must conclude that his failure to observe the maxim of quantity is due to his wish to observe the CP in some other way. You must work out why the CP should force your colleague to give more information than you requested.

(d) The failure to observe the maxim of quantity can be explained if you assume that your colleague also wishes to observe the maxim of quality. You conclude that for some reason he is confronted with a clash between these maxims (either he tells the truth or he gives you just the right amount of information).

(e) His reply is a compromise, which leads you to deduce that he is not sure that he has given you the exact time because the clock in the department is often inaccurate.

Thus, Grice's explanation for the nonobservance of the maxim of quality in this instance is that the speaker was faced with a clash of maxims. The speaker found himself unable simultaneously to observe the maxims of quality and quantity, signaled his dilemma by flagrantly failing to give the right amount of information, and prompted his interlocutor to draw an inference. A similar explanation might be offered for the following instance of nonobservance of the maxim of quantity. In this case, the second speaker gives less information than the situation demands (4):

A: Has Chris given up smoking? (4)
B: Well, he's certainly stopped buying his own.

B might simply have replied: 'No.' It would be possible to argue that his failure to do so stems from a clash between the maxims of quantity and quality (B does not know for sure whether Chris has given up smoking, and speaks only on the basis of the evidence he has). But this explanation is rather implausible. It is better explained by what Grice terms 'exploiting' the maxims.

2.2 Flouts which 'Exploit' a Maxim

According to Grice's theory, interlocutors operate on the assumption that, as a rule, the maxims will be

observed. When this expectation is confounded and the listener is confronted with the blatant non-observance of a maxim (that is, the listener has discounted the possibility that the speaker may be trying to deceive, or is incapable of speaking more clearly, succinctly, etc.), he or she is again prompted to look for an implicature. Most of Grice's own examples of flouts involve this sort of 'exploitation.'

Flouts which exploit the maxim quality, for example, occur when the speaker says something which is blatantly untrue or for which she or he lacks adequate evidence. In the 'wheel-clamping' example given in the opening section, an implicature is generated by the speaker's saying something which is patently false. Since the speaker does not appear to be trying to deceive the listener in any way, the listener is forced to look for another plausible interpretation. According to Grice, the deductive process might work like this (5):

(a) A has expressed pleasure at finding his car clamped. (5)
(b) No one, not even the most jaded masochist, is likely to be pleased at finding his car clamped.
(c) His passenger has no reason to believe that A is trying to deceive him any way.
(d) Unless A's utterance is entirely pointless, he must be trying to put across to his passenger some other proposition.
(e) This must be some obviously related proposition.
(f) The most obviously related proposition is the exact opposite of the one he has expressed.
(g) A is extremely annoyed at finding his car clamped.

The following example (6) works in much the same way, but this time involves what Grice rather vaguely terms 'generating a conversational implicature by means of something like a figure of speech.' The speaker is the *Peanuts* character, Linus, who comments wearily: *Big sisters are the crab grass in the lawn of life.*

(a) It is patently false that big sisters are crab grass. (6)
(b) Linus does not appear to be trying to make readers believe that big sisters are crab grass.
(c) Unless Linus's utterance is entirely pointless, he must be trying to put across some other proposition.
(d) This must be some obviously related proposition.
(e) The most obviously related proposition is that, like crab grass in lawns, big sisters are a bane.

What Grice's theory (at least as originally formulated) fails to say is why in this example one is expected to seek a comparison between crab grass in lawns and big sisters in life, whereas in the previous example one looked for a proposition which was the exact opposite of the one expressed. Developments in relevance theory (Sperber and Wilson 1986) could help to rescue Grice's theory at this point.

Examples of floutings of the maxim of relation are legion. The one in (7) is typical (it has to be assumed that it is clear in the context that B has heard and understood A's question):

A: Who was that you were with last night? (7)
B: Did you know you were wearing odd socks?

It would be tedious once again to work through all the steps in the informal deductive process—suffice it to say that A is likely to come to the conclusion that B is irritated or embarrassed by the question and wishes to change the subject. Again, Grice's theory fails to address a very important issue, viz. why does B choose to indicate only indirectly that she is irritated or embarrassed? After all, if A were a particularly insensitive person, there is the risk that she might ignore B's hint and pose the question again. B could remove that possibility by saying: *Mind your own business!* In the 1970s and 1980s much effort in the field of pragmatics was put into developing theories of politeness (see, for example, Brown and Levinson (1987) and Leech (1983)) which, proponents argue, 'rescue' Grice's theory by explaining the social constraints governing utterance production and interpretation (see *Politeness*).

The following example (8) illustrates a flout of the maxim of manner. It occurred during a radio interview with an unnamed official from the United States Embassy in Port-au-Prince, Haiti:

Interviewer: Did the United States Government play (8)
any part in Duvalier's departure? Did they, for example, actively encourage him to leave?
Official: I would not try to steer you away from that conclusion.

The official could simply have replied: 'Yes.' Her actual response is extremely long-winded and convoluted, and it is obviously no accident nor through an inability to speak clearly, that she has failed to observe the maxim of manner. There is, however, no reason to believe that the official is being deliberately unhelpful (she could, after all, have simply refused to answer at all, or said: *No comment*).

The hearer must therefore look for another explanation, and once again, there is nothing in Grice's theory to help explain the official's flouting of the maxim of manner. In this case, it is not a clash of maxims which has caused her to flout the maxim of manner in this way. Rather, it is occasioned by the desire to claim credit for what she sees as a desirable outcome, while at the same time avoiding putting on record the fact that her government has intervened in the affairs of another country. In fact, this exchange was widely reported and the implicature spelt out in news broadcasts later the same day: *Although they have not admitted it openly, the State Department is*

letting it be known that the United States was behind Jean-Paul Duvalier, 'Baby Doc's,' decision to quit the island. Nor can one sensibly ascribe the speaker's use of indirectness to any desire to be 'polite' (at least, in the normal sense of the term)—it appears to be motivated by the fact that she has two goals which are difficult to reconcile. This 'desire to say and not say' something at the same time is lucidly discussed by Dascal (1983), together with other social factors which lead speakers to employ indirectness.

The important thing to note in each of these cases is that it is the very blatancy of the nonobservance which triggers the search for an implicature. The same is true in each of the cases which follow.

3. Common Misrepresentations of Grice's Theory

There are many criticisms which can be made of Grice's work. However, there are four criticisms of his work which are made very frequently (particularly by nonspecialists) and which are totally unfounded. The first is that Grice had a ludicrously optimistic view of human nature: that he saw the world as a place full of people whose one aim in life was to cooperate with others. This is a complete misreading of Grice's work and is discussed in detail in another article (see *Cooperative Principle*).

The second unfounded criticism is that Grice was proposing a set of rules for good (conversational) behavior. This misunderstanding probably stems from the unfortunate fact that Grice formulated his maxims as imperatives. But it is clear from everything else he wrote on the subject that his chief objective was simply to describe linguistic behaviors which, by and large, people do observe in conversation unless they wish to generate an implicature, or are deliberately setting out to mislead, or are prevented for some reason from so doing (e.g., nervousness, an inadequate grasp of the language).

The third misconception represents Grice as believing that his maxims are always and invariably observed. This is simply false—such a claim would make complete nonsense of his theory. Discussing the maxims in his 1978 and 1981 papers, Grice refers to them as being:

> standardly (through not invariably) observed by participants in a talk exchange.

> desiderata that normally would be accepted by any rational discourser, though, of course, they could be infringed and violated.

The fourth misunderstanding is to confuse the different types of nonobservance of the maxim. This seems to come from an incomplete reading of Grice's articles, or a reliance on second-hand accounts (few general linguistics textbooks discuss any categories

other than flouting). A typical criticism of this order (this one is from Sampson 1982: 203) runs as follows:

> people often flout his [Grice's] maxims. To anyone who knew, for instance, my old scout at Oxford, or a certain one of the shopkeepers in the village where I live, it would be ludicrous to suggest that as a general principle people's speech is governed by maxims such as 'be relevant'; 'do not say that for which you lack adequate evidence' (!); 'avoid obscurity of expression, ambiguity or unnecessary prolixity' (!). In the case of the particular speakers I am thinking of ... the converse of Grice's maxims might actually have greater predictive power.

What Sampson is discussing is not the flouting of a maxim (that is, the blatant nonobservance for the purpose of generating an implicature). What he is describing is the unmotivated or unintentional nonobservance of a maxim, which Grice calls 'infringing' (see Sect. 4.2).

Grice was well aware that there are many occasions on which speakers fail to observe the maxims, even though they have no desire to generate an implicature, and even though his categories seem to cover all possible instances of nonobservance.

4. Categories of Nonobservance of the Conversational Maxims

In his first paper (1975: 49), Grice listed three ways in which participant in a talk exchange may fail to fulfill a maxim: the speaker may flout a maxim, 'violate' a maxim, or 'opt out' of observing a maxim. He later added a fourth category of nonobservance: 'infringing,' a maxim. Several writers since Grice have argued the need for a fifth category—'suspending' a maxim, and this category is considered along with the others. Having made all these distinctions, it is irritating to note that Grice himself does not always use the terms consistently, and that remarkably few commentators seem to make any attempt to use the terms correctly. The distinctions which Grice originally made are important for a full understanding of his theory. Flouting has already been examined in detail, and each of the others is now considered in turn.

4.1 Violating a Maxim

Many commentators incorrectly use the term 'violate' for all forms of nonobservance of the maxims. But in his first published paper on conversational cooperation (1975), Grice defines 'violation' very specifically as the *unostentatious* nonobservance of a maxim. If a speaker violates a maxim, he or she 'will be liable to mislead' (1975: 49).

Example (9) is an extract from an interaction between a headmaster and a pupil. It has already been established that the addressee, Hannah (a girl aged about 12), and her friend played truant from school. What is at issue now is where they went on

the afternoon in question and, in particular, whether they had been to Simon Connolly's house:

Headmaster: You know that I now know where you (9)
went, don't you?
Hannah: We were in the woods.

It is later established that Hannah's assertion that they were in the woods is true, but not the whole truth (she does not volunteer the information that they had first been to Simon Connolly's house 'for a little while'). But there is nothing in the formulation of Hannah's response which would allow the head-master to deduce that she was withholding informa-tion. This unostentatious violation of the maxim of quantity generates the (probably intentionally) mis-leading implicature that they went to the woods and nowhere else, that is, that they did not go to the boy's house.

Pragmatically misleading (or potentially pragma-tically misleading) utterances of this sort are reg-ularly encountered in certain activity types, such as trials, parliamentary speeches, and arguments. So regularly do they occur, in fact, that they could be seen as the norm for this type of interaction, and be interpreted in that light by participants. For more on this point, see Sect. 4.4.

Initially, it might appear that violating a maxim is the exact opposite of flouting a maxim. In the case of the violation by the schoolgirl, the speaker says something which is *true* (as far as it goes) in order to imply an untruth. In the case of a flout (as in the wheel-clamping example), a speaker may blatantly fail to observe the maxim of quality at the level of what is said, but nevertheless imply something which is true. All the examples of flouts which Grice himself gives are of this order. However, there is no principled reason to expect that an implicature will be *true*—a speaker can imply a lie almost as easily as he or she can say one.

4.2 Infringing a Maxim

As has been already noted, a speaker who, with no intention of generating an implicature, and with no intention of deceiving, fails to observe a maxim, is said to infringe the maxim. In other words, the non-observance stems from imperfect linguistic perfor-mance, rather than from any desire on the part of the speakers to generate a conversational implicature (this is the phenomenon which Sampson was describing above). This type of nonobservance could occur because the speaker has an imperfect command of the language, or because the speaker's perfor-mance is impaired in some way (nervousness, drunkenness, excitement), or because of some cogni-tive impairment, or simply because the speaker is constitutionally incapable of speaking clearly, to the point, etc.

4.3 Opting Out of a Maxim

A speaker opts out of observing a maxim by indicating unwillingness to cooperate in the way that the maxim requires. Examples of opting out occur frequently in public life, when the speaker cannot, perhaps for legal or ethical reasons, reply in the way normally expected. Alternatively, the speaker may wish to avoid generating a false implicature or appearing uncooperative. Here is an example from a British MP, who had been asked a question about talks he had had with the Libyan leader Colonel Gadaffi: *Well, honestly, I can't tell you a thing, because what was said to me was told me in confidence.*

When a speaker explicitly opts out of observing a maxim, she or he could be seen to provide privileged access into the way in which speakers normally attend to the maxims, which in turn offers prima facie evidence for Grice's contention that there exists on the part of interactants a strong expectation that, *ceteris paribus* and unless indication is given to the contrary, the CP and the maxims will be observed.

4.4 Suspending a Maxim

Several writers have suggested that there are occa-sions when there is no need to opt out of observing the maxims because there are certain events in which there is no expectation on the part of any participant that they will be fulfilled (hence the nonfulfillment does not generate any implicatures). This category is necessary to respond to criticisms of the type made by Keenan (1976), who proposed as a counterexample to Grice's theory of conversa-tional implicature the fact that in the Malagasy Republic participants in talk exchanges 'regularly provide less information than is required by their conversational partner, even though they have access to the necessary information' (Keenan 1976: 70). Keenan's examples do not falsify Grice's theory if they are seen as instances where the maxim of quantity is suspended. There is no expectation at all on the part of interactants that speakers will provide precise information about their relatives and friends, in case they draw the attention of evil spirits to them. Although the Malagasy may appear to be underinformative at the level of what is said, the uninformativeness is nevertheless systematic, motivated, and generates implicatures which are readily interpretable by members of that community.

Suspensions of the maxims may be culture-specific (as in Keenan's examples) or specific to particular events. For example, in most cultures, the maxim of quantity appears to be selectively suspended in, for example, courts of law, committees of inquiry, or indeed in any confrontational situation where it is held to be the job of the investigator to elicit the truth

from a witness. The witnesses are not required or expected to volunteer information which may incriminate them, and no inference is drawn on the basis of what they do not say (cf. the example of the schoolgirl in Sect. 4.1).

4.5 Distinguishing Between Different Types of Nonobservance

As has been seen, a flout is, by definition, so blatant that the interlocutor knows that an implicature has been generated. One very important point which Grice failed to address is how an interlocutor is supposed to distinguish between a violation, possibly intended to mislead, and an infringement, not intended to generate any implicature.

5. Conclusion

Grice first put forward his ideas concerning the conversational maxims in 1975, and his work continues to serve as the basis for much (probably most) work in pragmatics. Yet, as this article demonstrates, the theory is full of holes. Some of those holes have been or are being plugged, particularly by people working in politeness theory and in relevance theory, but the fact of the matter is that, unsatisfactory as Grice's work is, it has yet to be replaced by anything better.

Cooperative Principle

J. Thomas

The cooperative principle (CP) was first proposed by H. P. Grice in a series of lectures given in 1967. It runs as follows: 'Make your contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged.'

Already there is a problem. The way in which the CP is worded makes it seem as if Grice was telling speakers how they ought to behave. What he was actually doing was suggesting that in conversational interaction people work on the assumption that a certain set of rules is in operation, unless, that is, they receive indications to the contrary. In all spheres of life, assumptions are made all the time. For example, a car driver assumes that other drivers will observe the same set of regulations—the traffic system would grind to a halt if such assumptions were not made. Of course, there are times when a driver has indications that another driver may be liable to disobey the rules (a learner, a drunk, a person whose car is out of control), or that he may be following a different set of rules (a car with foreign number plates), and on these occasions the usual assumptions have to be reexamined or suspended altogether. And, of course, there are times when a driver wrongly assumes that others are operating according to the rules, and then accidents occur. So it is with conversation. When talking, speakers operate according to a set of assumptions, and, on the whole, get by, although inevitably misunderstandings and mistakes occur and sometimes a speaker is deliberately misled.

Grice's work has been, and continues to be, extremely influential. It has also been widely criticized and widely misunderstood. This article discusses various interpretations of his work, and argues in favor of the weaker of the two most common interpretations of the notion of 'conversational cooperation.'

In setting out his cooperative principle, together with its related maxims (see *Conversational Maxims*), Grice was interested in explaining one particular set

121

of regularities—those governing the generation and interpretation of 'conversational implicature.' For example, my brother comes in carrying an ice cream and says: *I didn't bother buying one for you*, to which I reply: *That's uncommonly generous of you!* On the face of it, my reply is untrue. However, the CP would lead him to assume that, in spite of appearances, I was making an appropriate comment on his behavior. He would therefore conclude that I had sacrificed a conversational maxim at one level, in order to uphold it at another. In other words, I had said something false, but implied something that was true. Grice argues that without the assumption that the speaker is operating according to the CP, there is no mechanism to prompt someone to seek another level of interpretation.

1. Different Interpretations of the Notion of Conversational Cooperation

Many critics of Grice's work on conversational implicature (Grice 1975, 1978, 1981) have been arguing at cross-purposes, and one important reason for this is that the very term 'cooperation' is misleading, since what in everyday terms would be seen as 'highly uncooperative' behavior, such as arguing, lying, hurling abuse, may yet be perfectly cooperative according to some interpretations of Grice's (1975) term.

Grice's own definition of the cooperative principle is ambiguous and inconsistent, and this has enabled both those who have adversely criticized his work and those who have adopted his theories to interpret what he has written to suit themselves. The majority of interpretations, it should be said, can be justified in terms of what Grice actually *wrote*, although some appear to be rather perverse interpretations of what he *meant*. What is striking, however, is how few of those who have drawn so heavily on Grice's theories appear to have noticed the many ambiguities which exist in his work, or, if they have noticed, have taken the trouble to define the way in which they themselves have interpreted the concept of conversational cooperation or are using the term 'cooperative.'

Outlined below are the most strikingly divergent interpretations of Grice's theory, followed by discussion of the different shades within each view. Common to all interpretations is the assumption that the speaker (S) and hearer (H) have some shared interest in conforming to certain linguistic and pragmatic norms, and in a *typical* conversation they do so. However, the question is what it means to conform to linguistic and pragmatic norms.

The most extreme view, which is introduced here only in order to dismiss it totally as a complete misinterpretation of what Grice was concerned to do, says that the maxims of quality, quantity, relation, and manner must at all times be observed at the level

of what is said. According to this view, the example given in the introductory section (*That's uncommonly generous of you!*) would be seen as an instance of uncooperative behaviour. Now, Grice states unequivocally that the ostentatious nonobservance of a maxim at the level of what is said (that is, what he originally defined as a 'flout'—see *Conversational Maxims*) in no way contravenes the CP. On the contrary, it is the mechanism which is required in order to generate an implicature.

The first view which is worthy of serious consideration (if only because it is so widely held) could be called 'real-world goal-sharing.' According to this interpretation, Grice is arguing that, in a 'normal' conversation, S and H actually have some shared interests which, by means of conversation, they 'jointly conspire to promote.' 'Real-world goal-sharing' refers to situations in which S shares with H some common aim or purpose beyond that of getting H to understand which proposition is being expressed or implied. According to this definition, compliance with the CP is possible only against a background of shared goals or interests, which might include (minimally) such local goals as 'keeping the conversation going,' but would generally involve a greater degree of 'real cooperation,' such as a shared interest in establishing the truth. Kiefer interprets Grice in this way:

> Now the Gricean maxims attempt to describe cooperative communication in which the participants strive after the same goal and are equally interested in achieving this goal, furthermore in which the participants have the same social status and finally in which the only goal of the communication is the transmission of information (in a maximally economical way).
>
> (1979a: 60)

According to a third school of thought, which could be called 'linguistic goal-sharing,' Grice intended the cooperative principle to have a much more limited scope. It applies only to the observance of linguistic conventions and presupposes no shared aim or purpose beyond that of establishing correctly S's illocutionary intent (that is, getting H to understand which proposition is being expressed or implied). In particular, it does not presuppose that the proposition which is expressed, entailed, or implied is necessarily polite, relevant to any of H's real-world (extralinguistic) social goals, or even presuppose (according to some interpretations) that it is truthful. This is the interpretation for which Holdcroft (1979) argues in his excellent discussion paper.

2. Real-world Goal-sharing View of Cooperation

Apostel (1980), Bollobás (1981), Corliss (1981), Kasher (1976, 1977a), Kiefer (1979a), Pratt (1977, 1981), and Sampson (1982) are among the writers who understand Grice to be using the term

'cooperation' in what is called here the 'real-world goal-sharing' sense: that is, they believe that when Grice speaks of cooperation he means that S shares H some common goal or purpose *beyond that of efficient message-communication*. (It should be pointed out that hardly any of these writers actually subscribe to the real-world goal-sharing view themselves—indeed, Apostel, Kasher, Kiefer, Pratt, and Sampson expres-sly dissociate themselves from it— but they do app-arently believe Grice to have been propounding it.)

According to this view, Grice's CP 'rests on the assumption of cooperation and shared purposes' (Kasher 1976: 201–2, 1977a). That Kasher (1977a: 332) is using 'cooperation' in the 'real-world goal-sharing' sense becomes clear when he says that the principles which he himself proposes, unlike Grice's: 'do not presume the existence of mutual ends for talk-exchanges, but merely the existence of an advantage for limited cooperation.' Kasher's counter-examples only serve as such to the goal-sharing view of cooperation. Sampson (1982: 204) likewise interprets cooperation in the very strong real-world goal-sharing sense, and attacks Grice's putative view with some vehemence, criticizing the CP on the grounds that it 'embodies assumptions which ... are very widely shared by students of language, but which imply a profoundly false conception of the nature of social life.'

Kasher, Kiefer, Pratt, and Sampson all believe that Grice's theory rests on a false view of the nature of participants in a conversation. Pratt (1981) caricatures the Gricean speaker as a 'cricketer-cum-boy-scout,' 'an honorable guy who always says the right thing and really means it!' All argue that Grice's explanation works only in the rather limited number of situations in which there is 'full cooperation.' They also consider that Grice's maxims apply only to 'cooperative communication in which participants strive after the same goal' (Kiefer 1979a: 60; see *Communication*), situations which they do not see as representing any sort of conversational norm (Pratt 1981):

> only some speech situations are characterized by shared objectives among participants. Clearly it is at least as common for speakers to have divergent goals and interests in a situation...there is no good reason at all to think of shared goals as representing any kind of natural norm in verbal interaction.

Apostel, Kasher, Kiefer, Pratt, and Sampson are right to reject social goal-sharing as a realistic model of human interaction. Their mistake, however, is in assuming that Grice was proposing it as such, a confusion which presumably stems from Grice's over-reliance in his 1975 paper on the analogy between linguistic behavior and other forms of cooperative endeavor, such as repairing a car. It is

perhaps significant that he does not pursue the analogy in either of his subsequent papers on the subject of conversational implicature (Grice 1978, 1981), but concentrates on linguistic behavior alone.

This article dismisses the notion of real-world goal-sharing, both as a realistic model of linguistic interaction and as a reasonable interpretation of what Grice was concerned to do. It argues in favor of the linguistic goal-sharing view.

3. The Linguistic Goal-sharing View of Cooperation

The dispute between the social goal-sharers and the linguistic goal-sharers can be summarized as follows. For the linguistic goal-sharers, 'conversational cooperation' is concerned with the relationship between what is said and what is implied: 'Use language in such a way that your interlocutor can understand what you are saying and implying.' For the social goal-sharers, 'conversational cooperation' means: 'Tell your interlocutor everything s/he wants to know.'

Those linguists who consider that Grice's theory does have some explanatory power have assumed that the CP and its maxims relate to a theory of linguistic interaction alone, rather than to a more general theory of social interaction, and all their examples are concerned with relating utterances to (implied) propositions. This implies a rejection of the real-world goal-sharing interpretation of cooperation in favor of linguistic goal-sharing, though lamentably few state this explicitly. Honorable exceptions to this stricture are Holdcroft (1979) and Weiser. The latter states his position unambiguously:

> The observation that people follow Grice's cooperative principle in conversation doesn't mean that people are cooperating with each other, but that they are conscious of a system of [regularities] which allows others to make 'strong inferences' about them ... If you ought to do something and you don't do it, others are entitled to make some inference about your omission. If you show that you're aware that you're not doing something you ought to, then other strong inferences will be made, depending on how you demonstrate your awareness...

For this group, the CP relates to a theory of linguistic interaction only, and is 'the general assumption on the part of H that S will not violate conversational procedures' (Grice 1981: 185). A further difficulty is introduced, however, when one considers precisely what constitutes for them 'a violation of conversational procedures.' It is clear that flouting, opting out, or unintentionally infringing a maxim do not constitute a 'violation of conversational procedures.'

What is not clear is whether Grice himself and/or the linguistic goal-sharers consider the unostentatious nonobservance of a maxim at the level of what

123

is said to be a 'violation of conversational procedures.' Consider example (1):

A: Do you know where Paul is?   (1)
B: Are the pubs open yet?

On the face of it, B has flouted the maxim of relation and has generated the implicature that he does not know for certain where Paul is, but it is very likely that he is at the pub. Now suppose that B actually knows full well where Paul is — he is at this moment breaking into A's toolshed. There is nothing whatever in the way in which B has responded which would indicate to A that B is implying something which is untrue.

The important question for the present discussion is: 'Was B being conversationally cooperative or not?' To answer 'no' would be to adopt the real-world goal-sharing fallacy—one knows that B was understood by A to have implied precisely what he intended to imply (viz. that he did not know exactly where Paul was, but was probably at the pub). The only reason for calling him 'conversationally uncooperative' in these circumstances would be on the grounds that he failed to tell his questioner exactly what his questioner wanted to know.

The linguistic goal-sharers would therefore have to reply 'yes,' arguing that the fact that what B implied was untrue has nothing to do with conversational cooperation or with a theory of implicature. The fact that B has deceived A is of no interest to the linguist (though it might be a suitable question for a social psychologist or a moral philosopher). However, to answer 'yes' in these circumstances makes it very difficult to say what, if anything, is not conversationally cooperative (that is, whether the concept of conversational cooperation is vacuous).

4. Conclusion

If one rejects the social goal-sharing interpretation of Grice's theory, then the concept of conversational cooperation does become trivially true. If, as some commentators maintain, even saying nothing or walking away is interpretable as 'opting out,' then it becomes difficult to find any instances of talk conducted in the presence of another person which do not *count* as cooperative.

Margolis (1979), in common with many others, has attacked Grice on the grounds that he provides only vague, sloppy, and circular notions of rules and discovery procedures. Margolis's criticisms (and similar ones proposed by Holdcroft 1979) that the CP is vacuous and unfalsifiable may be largely justified, but it would be a mistake to underestimate the insights which Grice has given into the process of utterance interpretation. To have pointed out what ordinary interactants take for granted is recognized within ethnomethodology, for example, as a major theoretical contribution. Altieri (1978: 92), commenting on Margolis's strictures, makes the following observation:

> with Grice, charges like Joseph Margolis' claim that his maxims are only principles of common sense may indicate his strength rather than his weakness. A *sensus communis* is not a bad ground on which to base our capacity to understand the pragmatics of meaning.

Grice can claim credit for asking a lot of very exciting questions, which have led linguists to think about language in a completely new way. But in the end, what is left is a set of very informal procedures for calculating conversational implicature, which cannot really withstand close scrutiny. On the other hand, flawed as Grice's work is, no one else, in the view of this writer, has yet come up with anything better with which to replace it.

Deaf Community: Structures and Interaction
J. G. Kyle

Deaf people are members of a social grouping who share a life experience and who have usually been educated in contact with groups of other deaf children. They have made a choice to associate with others from a similar situation. They form a community which differs from other communities in that deaf people do not live together in a community group (though they do intermarry), they do not work together, and they normally use their language in interaction in situations which are social rather than commercial. Interaction in the community is most commonly seen at the deaf club where deaf members gather (most evenings in city clubs, and less frequently in rural clubs). The deaf community can be described as a multipurpose community (embracing all features of personal and social activities), as distinct from the single-purpose societies in which hearing people now find themselves involved (e.g., sports, religious, political associations).

1. Membership

Three conditions are usually necessary for membership: a degree of hearing loss, sign language competence, and positive identification with other deaf people, the last being the most important.

Some people are 'born into' the deaf community as the children of deaf parents. However, only 5 percent of the community will have both parents deaf and a further 5 percent may have one parent deaf. Up to 20 percent will have a deaf sibling but this figure may include some of those in the 10 percent above (Kyle and Allsop 1982). Other deaf members are drawn from (nonsigning) families where there is no deafness and where isolation is a common early experience. When there is some contact with deaf adults, sign language will be acquired and used for effective interaction. For those with no contact with other deaf people in the early years, the communication problems can be immense.

One further factor which affects membership is that 90 percent of children born to deaf parents are hearing and do not usually remain involved in the community in adulthood.

2. Losing One's Membership

One cannot resign by nonattendance at the club, so there has to be a realignment of loyalties. For most deaf people this is unlikely—it would be very difficult to 'switch off' the deaf part and to identify more with hearing people. People living in isolated parts of the country would still be considered as part of the community even if they are very rarely seen by others.

Other circumstances could lessen the ties: in a mixed marriage a deaf partner may feel more drawn to the hearing society of the spouse and may forsake deaf company. Where members break the rules of the community they may be ostracized. One instance of this is divorce. Because of the small numbers of deaf people in any one area, marital breakup, particularly where there is infidelity, is likely to be public knowledge and one party may find it difficult to face the other member of the community.

3. Characteristics

Deaf people, while interwoven with society in everyday life, are only partly integrated into its framework. They achieve less in the education provided, have poorer jobs and wield less power. The commonest observation on employment is that people are 'underemployed rather than unemployed.' Deaf people generally have jobs in the unskilled and semiskilled occupations; very few are found in professional/managerial jobs. Significantly there are differences between White and non-White deaf people in employment with the latter less likely to be employed and likely to earn much less.

Jones and Pullen (1990), in a study of European countries, found evidence of underemployment, thwarted ambition, and even occupational segregation. Interestingly, they found that jobs were usually acquired through personal contacts rather than on the open market or through the rehabilitation or job-finding agencies.

Major studies of national samples in different countries highlight failure in education on a massive scale. Deaf children read poorly (profoundly deaf 16-year olds at an average reading age less than 9 years), speak unintelligibly, have limited lip-reading skills (Conrad 1979). They are less likely to go to college in the USA (Christiansen 1982) though they are more likely to go into further education in the UK (Kyle and Pullen 1985).

Not surprisingly then, deaf people in most countries have been considered in terms of their failures and are the subject of care, rehabilitation, social work, and service provision which is generally supplied without consultation. These supporting services may further weaken the decision-making possibilities and social power of the deaf community.

4. The Deaf Community as a Social Structure

There have developed two different levels of activity in the deaf community. On one level there is official provision and associations. On the other level are deaf people, their interaction, and what was once

described as 'their secret language' (see *Sociolinguistics of Sign Language*).

In most countries, there is a network of Deaf Clubs and societies. Most have their origins in the associations initiated by deaf people but organized by hearing people. Some remain as charitable bodies with their own hearing-dominated board of management. Some are still dominated by the religious groups. In the nineteenth century, these associations catered for the moral and spiritual welfare of deaf people as well as providing further education and often providing training for a trade. Many were stifling of initiative being wholly controlled by hearing people who could sign or by partially-hearing people who could function well in the hearing world.

This infrastructure was seldom part of the 'Deaf Way' (Deaf culture). The interaction among deaf people takes place on a different plane (the social club) which only occasionally interfaces with this overt hearing organization. From the social club deaf people organize activities, care for the children and for the elderly, arrange trips, and create interclub events. The larger the membership the wider the range of activities (both sports and social) and the greater the degree of social skill required. In many respects the Deaf social club functions as the 'heart of the village of deaf people.'

5. Hearing People

Deaf people may accept that there is a place for hearing people in the deaf club. The question of whether they belong in the deaf community is rather more difficult to answer. People with a hearing 'attitude' are generally excluded. However, the hearing interface which deaf people need is seldom adequate—all over the world there is a lack of trained interpreters.

6. The Culture of Deaf People

Until recently there was no single sign for 'culture.' Deaf people described the differences in their lifestyle, in terms of the sign for 'possession' linked to the sign for 'deaf'—generally glossed as Deaf Way. Although incomplete, current attempts to describe the culture highlight certain behavioral patterns. These include:

(a) *Attention-getting and Touch.* Deaf people touch each other more than do hearing people. Attention-getting is often done by touch, rather than by the use of vocatives. When a person is out of reach, other devices are used such as waving or even stamping the floor or banging on the table. When the attention of a whole audience is required the lights of the room may be flashed.

(b) *Turn-taking.* The signer during a conversation may look away from the viewer indicating a wish to hold the floor. The viewer may attempt to break into the conversation by waving with a wrist action or touching on the arm.

(c) *Breaking into a Two-person Conversation* is also rule-bound. The third person, who is interrupting, has to apologize to the second signer, not to the person with whom he or she wishes to converse; only then can a message be given to the first person.

(d) *Turning Away* is generally an insult and when attention is called away, the signer has to adopt a convention to ensure that the viewer is not upset. This is often done by signing HOLD-ON or holding the viewer's arm while turning away.

(e) *Privacy and Confidentiality* are more difficult to achieve in the deaf community because of the visibility of conversations. Topics which are personal will not be discussed in the social area of the deaf club unless they are already common knowledge.

Customs exist in weddings, funerals, and in timekeeping (where a myth that deaf people have a different concept of time, can be dispelled). Many traditional stories within the deaf community relate to development in the adversity of oralism or of education. Experiences such as those of deaf children in UK schools in the early twentieth century, where they were referred to by number rather than by name are passing into the folklore of the culture. Frequently deaf people will use humor to exorcise some of the awful experiences. Such stories are 'traditional' among deaf people at gatherings.

Deaf games are also another feature of cultural life. Parties are not characterized by loud music but rather by the gradual unfolding of increasingly complex deaf games.

7. The Status of the Deaf Community

Deaf communities are in different stages of development in different countries. Everywhere there is an increasing awareness and evolving pride in being deaf, but this is still based on an inadequate knowledge base. Such a lack of empowerment should be a thing of the past in view of the rights afforded to deaf people in Sweden, in view of the European Parliament's recent recognition of the sign languages of the member states, or in view of the major events which took place in Washington in March 1988.

There has been no spreading revolution nor any major restatement of the rights of deaf people in any country.

Dialogism

T. A. Marshall

It was in the early 1980s that the term 'dialogism' started to enter the debates and the changing vocabularies of literary and cultural studies in western Europe and America. It did so via translations of the work of the Russian scholar M. M. Bakhtin. Incomplete as this body of work still remains for the western audience, its rate of assimilation and wide appeal continues to be remarkable. The history of its reception, when it is written, will very likely situate this appeal within the latter end of concerted challenges, in the postwar period, to a dominantly humanistic conception of human culture. It has also been favorably taken up by strands of post-1968 Western Marxism and multiethnic forms of cultural studies. This is all in marked contrast to the immediate reception of Bakhtin's work in Russia in the late 1920s and early 1930s. The dangers of Soviet intellectual life are sometimes thought to have obliged Bakhtin to publish under the names of friends and associates more in favor with the authorities. The works under the names of V. N. Voloshinov (see *Voloshinov, Valentin Nikolavic*) and P. N. Medevedev are now accepted by some as Bakhtin's own (see *Bakhtin, Mikhail M.*).

1. Terms

Besides 'dialogics' as a specific philosophical principle, Bakhtin offers a range of distinct but related terms: 'heteroglossia,' 'monologic,' 'polyphony,' 'reported speech,' 'multi-accentuality,' and 'carnivalization.'

2. Dialogism

Writing against idealist accounts of the relationship between language and consciousness, Bakhtin argues for a reversal of the more usual way of viewing the relationship between the world of signs (or ideology and culture) and consciousness. Within idealist philosophies of culture, signs are viewed as the means through which the inner thoughts and feelings of individuals are expressed. This view makes the sign into the external, objective manifestation of the inner world of consciousness; it puts consciousness prior to language. Such a conception is unacceptable to Bakhtin, for whom exactly the reverse is the case: 'Consciousness can arise and become a viable fact only in the material embodiment of signs.' (Voloshinov 1973.) In other words, not consciousness but language is the logically prior term. It is constitutively intersubjective, therefore social, and precedes subjectivity. To have a subjectivity, to be a person, is to have in the first instance entered via language into dialogue with others. Bakhtin's categorical claim that each of us is constituted dialogically thus strikes at received humanist assumptions that each of us is an autonomous individuality, clearly separable from other selves, authentic in privacy only, free of external influences. The self, for Bakhtin, is social and collective no less, for it is literally made up of what he calls 'languages,' the 'voices' spoken by others, all of which enter in and contend within oneself from birth onwards. In this way also Bakhtin conceives of ideology as inescapable in every movement of thought and speech, of words-laden-with-values. Indeed his list of the sources of ideology is deceptively short and simple: scientific statements, religious symbols and beliefs, works of art (see *Ideology*).

For each person, however, the list will always be longer than this and in principle it will be impossible to conclude or subordinate its items. Even within the same society the diversity might include parents, reading, other persons, nationality, class, color, profession, social circles, generation, epoch, political affiliation, educational biography, family; and each listing could break down ever further. Where, amid this diversity, does one rule out all voices but 'my own'? Short of an artificial pretense, it is impossible to do so, for this diversity is what Bakhtin means by 'polyphony': it constitutes each of us, and can even be taken to mean that each one of us is a variable compound of a 'we' and an 'I.' This same principle of

127

multiplicity holds true for texts as well as persons. Bakhtin distinguishes between a 'heteroglot' text, that is, one composed of many voices, and a 'monoglot' one, one which is singular in its discourse and view of the world (see the essay 'Discourse and the Novel' in Bakhtin 1981). Better known is the identical distinction drawn between the 'dialogical' and 'monological' text, between Dostoyevsky and Tolstoy, in Bakhtin's pioneer work (1984). Comparable to this distinction, and compatible, is Barthes's theory (S/Z 1970) that all narratives are composed of an interweaving of voices that cannot finally be structured into any controlling hierarchy.

3. Heteroglossia

Before an exploration of the literary and linguistic aspects of Bakhtin, and by way of stressing the broad base of his appeal to Western theorists, this definition of 'heteroglossia' by a writer in the field of communication studies is relevant:

> Bakhtin's basic scenario for modelling variety is two actual people talking to each other in a specific dialogue at a particular time and in a particular place. But these persons would not confront each other as sovereign egos capable of sending messages to each other through the kind of uncluttered space envisioned by the artists who illustrate most receiver-sender models of communication. Rather, each of the two persons would be a consciousness at a specific point in the history of defining itself through the choice it has made — out of all the possible existing languages available to it at that moment — of a discourse to transcribe its intention in this specific exchange.
>
> (Newcomb 1984)

Bakhtin is always concerned to set this 'heteroglossia,' in society as well as texts, in a context of power relations. For every social group relates differently to the linguistic community, each in a continuing struggle to draw meanings into their own subculture and re-accent them for their own purposes. The forces with social power in society will always attempt, in their own interests, to extend their control; subordinate interests tend either to resist, or negotiate, or even to evade the dominant power. In Bakhtin's words (1981), heteroglossia is 'that which ensures the primacy of context over text...all utterances are heteroglot in that they are functions of a matrix of forces practically impossible to recoup, and therefore impossible to resolve. Heteroglossia is as close a conceptualization as is possible of that locus where centripetal and centrifugal forces collide.' 'Centripetal' here means a force working towards a unified language, to which the 'centrifugal' is a counterforce tendency, an undermining of such ambitions and pretensions. Heteroglossia, then, is the representation of social differences textually. Precisely as voices and meanings will be in conflict with each other, the heteroglossia (of a written or television text, for example) enables such texts to engage in dialogic relationships with text users.

4. Langue and Parole

Historically Bakhtin's ideas are situated within the intellectual movements of Formalism and Marxism, but typically in a relationship to both of polemic and critique. Marxist premises, for example, are used to criticize Formalism's assumptions of the autonomy of art and 'literariness'; but contrariwise, the formal characteristics of works of art are also insisted upon by Bakhtin in cautioning Marxism against crude arguments from ideological contexts. The basic disagreement with Formalism, however, and indeed later with Structuralism, emerges in Bakhtin's confrontation with the structural linguistics of Ferdinand de Saussure. In *Marxism and the Philosophy of Language*, Voloshinov objected primarily to Saussure's distinction between *langue*, the system of rules underlying and structuring any utterance, and *parole*, speakers' actual linguistic performances. In terms of how language works this means that Formalists and Structuralists stress the 'system,' the synchronic whole which enables meaning to emerge within individual utterances. Bakhtin did not reject the existence of the system, but he argued that it offers no way of explaining how particular meanings are generated within particular utterances. In his concern to understand language as an abstract system, Saussure ignored the 'diachronic' nature of language in actual use: 'the actual reality of language — speech — is not the abstract system of linguistic norms...but the social event of verbal interaction implemented in an utterance' (Voloshinov 1973).

As a diachronic event, language in actual use is also a dialogical event, in that the meaning of an utterance is given not by the intention of an individual, but by its context. It is always addressed to another and, likewise, because language precedes each addressee, is already quoting another. Saussure's emphasis on *langue*, according to Voloshinov and Bakhtin, failed to take account of the fact that from the viewpoint of the speaker's consciousness and actual speech in social intercourse, there is no direct access to the abstract system. Thus speech is as much a social process as a rule-governed performance, always taking place within the field of cultural relations. For this reason Bakhtin conceptualized language not as a system producing meaning solely through the relationship of sign to sign, but as a field of possibilities. Traditionalist objections to the structuralist approach, which are not shared by Bakhtin, resist the dispersal of meaning across a field of signifiers precisely by insisting upon meaning residing in the intending subject. This is the humanist approach: it resists what has become called the decentering of the subject, and insists upon meanings residing in words or statements guaranteed by

authorial-utterer intentions. In Bakhtin, the speaking subject as the guarantee of essential meanings is indeed decentered. But this occurs within the process of cultural negotiation that determines which possibilities of meaning are actually realized. The sign is a social fact precisely because it responds to differences and balances of power: 'each word ... is a little arena for the clash and criss-crossing of differently orientated social accents. A word in the mouth of a particular person is a product of the living interaction of social forces.' Voloshinov (1973). A good example of the sign as an arena is the multiple currency of the word 'patriotism' in the late eighteenth-century English political context. As Hugh Cunningham has shown, at the time both the right and the left ends of the political spectrum—those defending the status quo and those demanding radical reform—sought to present themselves as the truly patriotic voice (Cunningham 1981: 12). But this example aside, the general point is that every sign has the potentiality to carry the inflections of different social groups. Hence for Bakhtin the domain of ideology coincides with the domain of signs.

Bakhtin's critique of abstraction in Saussure may also be extended to other major Western theorists of language. Chomsky is another important point of reference in this respect, for his difference from Bakhtin highlights the latter's characteristically dialogical thrust of cultural polemic. The Chomskyan distinction, for example, between 'competence' and 'performance' assumes a transcendent grammar to which actual speech performance can only be imperfectly compared. This model appears to provide a criterion of linguistic correctness, for Chomsky has stated that: 'Any interesting generative grammar will be dealing, for the most part, with mental processes that are far below the level of actual or even potential consciousness; furthermore, it is quite apparent that a speaker's reports and viewpoints about his behavior and competence may be in error' (Chomsky 1965: 8). Now Bakhtin would not acknowledge any such criteria of correctness, save only in instances of language instruction itself, for to do so is to move to 'correct' matters that must be judged and understood by ideological criteria. The social and political consequences of such an abstract linguistics, in Bakhtin's vocabulary, are centripetal, and need to be perceived against the backdrop of the very heteroglossia they seek to deny. In other words, distinctions between language and speech, and between synchrony and diachrony (which are traced by Bakhtin back to Cartesian rationalism and Leibniz's conception of a universal grammar) are themselves contextualized by Bakhtin—in a shrewd polemical move—and seen to serve the needs of sociopolitical centralization. The social home of Cartesianism is State policy; it services rationales to exclude bi- and multilingual education; it occurs in

language requirements attaching to immigration restrictions; it appears in tensions between nonstandard and standard dialects (which themselves are fictions that help to create a transcendent 'standard'). In general, as a form of monologism, it militates against change and linguistic creativity. A relevant point of comparison here is Roland Barthes's early work, his demystification of cultural and historical artefacts that pass themselves off as more or less natural, inevitable phenomena. In *Writing Degree Zero* (1967) Barthes examined the intellectual value, and virtue, attached in France to *la clarté*, or lucidity. Lucidity, he pointed out, is widely supposed to inhere in the French language as a somehow self-evident virtue which all must recognize. In Barthes's analysis, *la clarté* is located as historical phenomenon, specific to court usage in the seventeenth century. It was falsely universalized through agencies such as the Port Royal grammarians, who actually imposed their own idiom as the paradigm of the language as a whole. Barthes dubbed *la clarté* class idiom, and exposed its political and rhetorical value, its connections to power. *La clarté*, in Bakhtin's term, is a centrifugal force.

5. Multi-accentuality

Saussure is famous for his articulation of the arbitrary nature of the sign, by which he meant the arbitrary relationship between the sound–image and concept of the sign, signifier and signified (see *Saussurean Tradition and Sociolinguistics*). In the absence of intrinsic properties, the values that signs carry, Saussure maintained, 'owe their existence solely to usage and general acceptance,' that is, to convention. Bakhtin's acknowledgement of the arbitrariness of the sign is cautious nevertheless, and once again polemical. For he understood Saussure to be claiming that a verbal sign is ultimately a mental construct, that the acoustic image and the concept are both contained in an arbitrary closed system no different in principle from systems of mathematical signs. The idea of the arbitrariness of the sign can, Bakhtin cautions, encourage an insensitivity to the ideological meanings that give signs their content. For crucial to Bakhtin's sense of the social life of the sign is the fact that every sign without exception is capable of signifying different values. In addition to sound–image and concept an 'evaluative accent' comes into play in our use of signs. Signs possess 'an inner dialectic quality,' or 'multi-accentuality':

> Class does not coincide with the sign community, i.e., with the community, which is the totality of users of the same set of signs for ideological communication. Thus various different classes will use one and the same language. As a result, differently oriented accents intersect in every ideological sign. Sign becomes an arena of the class struggle. This social *multiaccentuality* of the ideological sign is a very crucial aspect. By and

large, it is thanks to this intersecting of accents that a sign maintains its vitality and dynamism and the capacity for further development. A sign that has been withdrawn from the pressures of the social struggle — which, so to speak, crosses beyond the pale of the class struggle — inevitably loses force, degenerating into allegory and becoming the object not of live social intelligibility but of philological comprehension... The very same thing that makes the ideological sign vital and mutable is also, however, that which makes it a refracting and distorting medium. The ruling class strives to impart a supraclass, eternal character to the sign, to extinguish or drive inward the struggle between social value judgments which occurs in it, to make the sign uniaccentual. In actual fact, each living ideological sign has two faces, like Janus. Any current curse word can become a word of praise, any current truth must inevitably sound to many other people as the greatest lie. This *inner dialectic quality* of the sign comes out fully in the open only in times of social crises or revolutionary changes.

(Voloshinov 1973: 23)

This amounts to a profound refusal to see language as a closed system of self-identical forms, that is, the one-to-one correspondence of a signifier to a signified. While acknowledging that the sign is not stable or fixed, Voloshinov insists nevertheless that multiplicity of meaning is a function of the sign's multi-accentuality, its openness to different evaluative orientations. The somewhat dated and historically obligatory Marxist orthodoxy of the class struggle should not deter us from realizing the relevance of this model to any analysis of the signs of power. The metaphor of an arena of power applies just as cogently to any conflict of interests carried by signs; it gains appropriateness from the fact that contending social forces always seek to fix the 'meaning-potential' of signs with an evaluative accent according to their interests and objectives. Until recently, for example, a 'norm' of a sort existed—not least in academic and other forms of 'serious' expository prose — to use the pronoun 'he' to denote not a male person but any person, male or female. This is a uni-accented sign that constructs and sustains a norm in which patriarchal interests are affirmed. As with any sign, its value is not simply a linguistic value but an ideological one as well, for it is not always possible to choose to employ alternatives to protocol. Another example of a uni-accented sign (cited by Hartley 1982) is Sir Thomas Elyot (1531) describing democracy as 'a monster with many heads.' It was because democracy was such a political threat to the monarchical society of the day that Elyot's discourse strove to make it appear to be intrinsically endowed with negative attributes. Even as ideological values enter this representation, the uni-accented sign functions to *naturalize* it as an unchangeable fact. As Hartley puts it: '... since signs are necessarily multi-accentual, any discourse which

seeks to "close" their potential, and to prefer one evaluative accent over another is ideological: such discourses present evaluative differences as differences of fact' (1982: 124). Any sign can in principle inflect in ways contrary to Saussure's rubric of 'general acceptance,' a formula to Saussure's rubric of 'general acceptance,' a formula that somewhat understates the realities of the power struggle within society: kings in their time have also been seen as monsters.

6. Changing Signs: The Example of Literature

A significant moment in Bakhtin's reception in the West was marked in 1976 with the publication of *Keywords* by the socialist critic Raymond Williams. The volume's subtitle *A Vocabulary of Culture and Society* is an intertextual reference to an earlier work by Williams himself (*Culture and Society 1780–1950, 1958*), in which he undertook to discriminate the historical ideas carried by the sign 'culture' in its general modern uses. *Keywords* continued this inquiry, concentrating on and recovering the changing meanings carried in English by such terms as 'industry,' 'nature,' 'organic,' 'mass,' 'leisure,' and many others. This inquiry, notably, is not subtitled as a dictionary but a vocabulary. It thus accords exactly with Bakhtin's sense that words come not out of dictionaries but out of concrete dialogic situations. For Bakhtin the distinction between dialogic words (or 'utterances') and dictionary words is a distinction between theme and 'meaning.' 'Meaning, in essence, means nothing; it only possesses potentiality—the possibility of having a meaning within a concrete theme' (Voloshinov 1973: 101). Words acquire meaning exactly and only by the way they always recall earlier contexts of usage, whether covertly or overtly. This point bears crucially, for example, on Williams's entry in *Keywords* on the sign 'literature':

> What has then to be traced is the attempted and often successful specialization of 'literature' to certain kinds of writing... Clearly, the major shift, represented by the modern complex of 'literature,' *art, aesthetic, creative*, and *imaginative* is a matter of social and cultural history. 'Literature' itself must be seen as a late medieval and Renaissance isolation of the skills of reading and of the qualities of the book; this was much emphasised by the development of printing... Then 'literature' was specialised towards *imaginative writing*, within the basic assumptions of Romanticism... Significantly in recent years 'literature' and 'literary,' though they still have effective currency in post-C18 senses, have been increasingly challenged, on what is conventionally their own ground, by concepts of *writing* and *communication* which seek to recover the most active and general senses which the extreme specialization had seemed to exclude.
>
> (Williams 1976: 150–4)

Here Williams is discriminating a uni-accented sign under challenge, thus turning multi-accentual. The history he charts has had implications for teaching

and pedagogic practice in the humanities. It is not a historical accident that in the twentieth century the institutionally sanctioned study of literature in the West has greatly concentrated upon formal and textual aspects at the expense of the historical and contextual. In a distinctly Bakhtinian move, Williams is countering the latter tendency by recovering the history it excludes: he opens the sign. The elevation, and evaluation, of 'literature' into a pure essence uncontaminated by history, or modernity, is itself a historical fact: it favored and for a long time stabilized the concepts of practical and new criticism.

A brief historical survey of the origins of practical and new criticism is relevant here, for these discourses display, in Bakhtin's sense, centripetal tendencies. Nineteenth-century historical and philological research based itself on European vernacular literature: texts were regarded, on analogy with biblical and Classical texts, as documents in the history of a culture and language and as contributions to a more newly found sense of European national identity. It remains, however, something of a paradox that the upshot of this extensive research was an emergent awareness of patterns of meaning and form that apparently transcended specific cultural or linguistic contexts: patterns, that is, that seemed capable of being described as universal. They were somehow autonomous idioms at once engaging and transcending particular languages and cultures. To later authoritative readers, within this tradition as diverse as Victor Shklovsky, F.R. Leavis, and Cleanth Brooks, something like an intrinsic and codifiable language of literature seemed to exist in these texts. In this broad context 'literariness' accommodated 'defamiliarization' (Shklovsky 1917), 'canonization' (Leavis 1948), and 'paradox' (Brooks 1947). The notion of 'literariness' implies a linguistic domain constituting 'literature' in essence, in opposition to what it constructs as 'ordinary discourse.' In fact, however, the distinction and the value-judgment it carries has proved at once tenacious and, in theoretical terms, difficult to sustain. Within a Bakhtinian scheme, for example, these essentializing tendencies privilege text over context. 'The text itself' is a piece of Formalist critical parlance that leaves scant room for social changes in language practice to play an explanatory role vis-à-vis the text-as-object. (By contrast, a phrase such as 'ordinary discourse itself' sounds merely odd.) The text's mediation via the authoritative subjectivity of the professional critic (another relatively recent historical development in fact), until recently, at least, has played a role in limiting, or marginalizing, the role of the reader. The favorable reception accorded to Bakhtin has had much to do with his encouragement to recontextualize the 'literary' as social discourse, and an agenda to emphasize literary history, readers, social institutions, the academy included. It coincided with a revived post-1968 Marxism committed to historical critique; with emergent feminism; with calls for interdisciplinary work with an ever-present popular culture and the newer visual media.

7. Genre

The question of genre in Bakhtin remains open to considerable interpretation. His concerns here go far beyond Formalist interests in stylistic variations between works or between particular authors. As Clark and Holquist have described it, genre for Bakhtin is 'a crystallization of the concepts particular to a given time and to a given social stratum in a specific society' (1984: 275). So, for example, historically variable time–space configurations, or 'chronotopes,' are indices of cultural diversity. Different historical concepts of time and space play a role in distinguishing narrative genres. In the Greek romance, for example, time involves no clear progression and place remains mere background. In the romance, circumstances may help or impede the hero, but never change him (or her). An example could be Plutarch's *Lives,* in whose chronotope character is a given: Camillus simply lives his destiny out, manifesting unchanging, essential qualities. In the novel's chronotope, by contrast, the social world enters action, thought, and choice, defining and shaping irreversible possibilities. In the novel, unlike the epic, there is always a noncoincidence between hero and environment, a gap between self and social categories. It is this sort of distinction that Bakhtin makes when differentiating genres. In another broad link between social concepts and genre, Bakhtin reads Rabelais's work as articulating a disintegration of inherited religious and institutional dogma which accords hierarchical primacy to transcendent spirit over matter. Rabelais's uncompromisingly material presentation of the human body is read by Bakhtin as disintegrating fixed social configurations and creating new ones, infiltrating matter with new penumbras of meaning.

Bakhtin certainly prefers some forms of literature to others, according to his distinction between centrifugal and centripetal. He is most of all unforthcoming on drama, the one form above others which in the West has often been viewed as the political art par excellence. But despite the superficial polyphony, the dramatist still imposes upon his or her characters what they say and how they say it. The least satisfactory part of the work on genre, however, is perhaps Bakhtin's implicit submission that all poetry assimilates to the lyric and is centripetal in tendency. It is arguable that these are moves by Bakhtin within a larger frame of strategic objectives, not least of which is to contest the centripetal tendencies of literary critics themselves, and by extension the hegemony of poetry as the supposed essence of literary form. It is certainly noteworthy

that Bakhtin's reception in the West coincides in time with moves, even within practical criticism, to account for the language of prose fiction with an attention to detail hitherto mainly reserved for poetry (Lodge (1966) was a pioneer work.) The other strategic move is to introduce a study of novelistic discourse which in scope and time extends well beyond what is usually understood by the novel. Bakhtin valorizes 'novelistic discourse' as the form, par excellence, that in its very fabric opens itself to heteroglossia: ideally, it is the most comprehensive denial possible of the absolutism of a single and unitary language. As Bakhtin explains (1984: 47–77), this involves not at all a merely pell-mell simulacrum of people's speech, but a 'representation' of speech. The paradigm of novelistic discourse that he finds in Dostoyevsky incorporates the copresence both of the author's and the character's fully-fledged voices. The speech of the characters is dialogized exactly by the author's inclination and ability to dialogize, and thus relativize, his own relation to their words. As Wayne C. Booth introducing Bakhtin (1984), puts it: '...techniques [are viewed] as performing their highest service by observing the autonomy of the novel's characters...all are treated not as objects serving the author's plans, but as subjects, ends in themselves, defying any temptation the author may have to fit them into his [or her] superior plans' (Bakhtin 1984, Introduction by W. C. Booth: xxiii). The diverse consciousnesses and voices making up the novelist's thought are bound up in a struggle with one another for dominance; no one voice is the bearer of ultimate conceptual authority. (It is typical also that the title of the great study of Dostoyevsky implies a body of unresolved problems, an openness to dialogue.) This is technique that discards any external epistemology of knowing, based on 'objectification.' As subjects rather than objects, Dostoyevsky's characters are never exhaustively known, defined, or finalized, as they would be, were any such authority to have the first and last word. Like the genre itself, personality in the novel is always unfinished and incomplete, as opposed to personality in the epic, where it is finished and complete at the outset.

Accordingly, the techniques that most interested Bakhtin were the resources of narrative in prose to incorporate languages other than the author's or the reader's. The second half of *Marxism and the Philosophy of Language* (1973a) is an investigation, rich in working examples, of 'indirect' and 'quasi-direct' discourse, multileveled speech acts in which more than one voice participates. They are studied not just as grammatical and syntactic categories, but as ways in which one speaker or writer can orientate himself or herself to the words of another. There have been, to date, some sophisticated and detailed studies of multivoicedness in prose, based specifically on the numerous forms of 'free indirect discourse' (often abbreviated to FID), where the vocabulary and prosody of a character's speech are rendered without quotation marks in what is nominally the narrator's voice; James Joyce's short story 'Eveline' in *Dubliners* is a good example (for studies of the variations of FID, see McHale 1978, Banfield 1973, Rimmon-Kenan 1983). A good first introduction to this kind of technical issue is provided by Bakhtin's own essay 'Discourse in the Novel' (1981), which uses Dickens's *Little Dorrit* as exemplary of the novel's ability to represent an interanimation of socio-ideological languages. In this essay Bakhtin makes the important point that the dialogic nature of the novel can be either open or closed: the author can either let heteroglossia speak for itself or can impose a privileged authorial metalanguage. On the premises of the argument the single-voiced monological text exists as a suppression of dialogic activity; the author's superior voice has for a long time served as a critical fiction, closely resembling idealism's inner world of consciousness, and placed historically in Williams's survey of 'literature.' But the promise extended by Bakhtin is that attention to technique and linguistic aspects can enable even 'omniscient' ideological voices in prose to be read and produced by readers as the suppressive and naturalized voices that they are. An (admittedly virtuoso) analysis of just this kind was offered by Barthes (1970), in a reading of 'Sarrasine,' a short story by Balzac, Barthes's insistence on the supremacy of 'writerly,' *scriptible*, literature over 'readerly,' *lisible*, literature has a good deal in common with Bakhtin's preference for polyphony over single-voiced texts. In both cases the latter term is derived and extracted from the former; in both cases value-judgments favoring polyphony are made explicit and defended within a broader cultural polemic. An important part of this polemic, it should be added, is that Bakhtin never treats the monological as a species of merely theoretical error or illusion. For as just stated, it is a form of discourse itself with real, albeit mystifying effects, and a theory of language should offer an account of these. Centrifugalism remains implicitly an ethical imperative, for the monological text is a partial report.

8. Carnivalization

Bakhtin never intends us to understand dialogism as an equilibrium of voices, a common ground of give-and-take, or a pluralism of amicable disagreements. He insists on power inequalities, on fierce and even intractable social struggle. 'Carnivalization,' a term drawn from his study of Rabelais, is his term for dialogic activity of an especially intense, iconoclastic kind. It is a world of head-on confrontations between voices and energies which otherwise only rarely

surface within the existing social and ideological arrangements.

The carnival culture that Bakhtin described (1968) in the works of the medieval writer Rabelais is a space of urgently emergent voices outspeaking and overturning official hierarchies, pieties, and prohibitions. The carnival abolishes the seriousness of life; nothing that is permanent or completed survives, the solemnity of all ready-made ideas and truths collapses. In this world-turned-upside-down officialdom's gravitas is mocked and absorbed back into a collective 'grotesque body' of laughter, excess, offensiveness, and degradation. A collision and inversion of languages—the high, validated language of classicism and the low, parodic vernacular—is perhaps the core event of carnival rule-breaking. It is part of the spectacle of differentiated forms of the self—degraded back to a level of sheer materiality on which everyone for once is equal. As a form that never forgets the carnival spirit, the novel for Bakhtin is less a genre than an antigenre. It recognizes, often in parody, the arbitrariness and conventionality of forms and norms; instead of knowing, it asks how we know. In Bakhtin's scheme the carnival-novelistic spirit has old historical foundations, and includes the ancient Menippean satire with its direct roots in the world of saturnalian folklore. Another historical form is the genre of the Socratic dialogue, discourse in which the discovery of truth is conducted as an unfolding exchange of views rather than as an authoritative monologue. Great interest continues to be shown in Bakhtin's provocative study of Rabelais: arguments continue as to whether carnival is a conservative or a revolutionary force, a means of containment and surveillance tolerated (or even sponsored) by officialdom itself, or genuinely unlicensed life. A valuable summary of the present debate is given in recent work by Stallybrass and White (1986).

Discourse

A. McHoul

'Discourse,' used as a mass noun, means roughly the same as 'language *use*' or 'language-*in-use*.' As a count noun ('a discourse'), it means a relatively discrete subset of a whole language, used for specific

social or institutional purposes—as in 'the medical discourses of the middle ages.' Occasionally the 'count' usage becomes 'massified'—as in 'Aristotelian scientific discourse' or (and therefore ambiguously) 'the discourse on childhood.' The second usage carries the implication that discourse is a way of ordering categories of thought and knowledge, echoing the 'ordinary' meaning of 'a discourse' as a kind of text or treatise. In some critical branches of philosophy and semiotics, the term 'discursive' carries with it the sense of 'textually or linguistically produced.' Thus madness, for example, may be referred to as 'discursively constructed,' to show that it does not exist as a 'real fact' in the world but is fabricated within certain forms of knowledge or 'disciplines,' often for particular political purposes.

1. The Term(s)

Already the term 'discourse' is seen to be being used extremely diversely, both within linguistics (and its subdisciplines) and within other areas of the social sciences and humanities, particularly sociology (historical reasons for this are dealt with by Hodge 1984). So while it will always be possible to find the term being used in other ways, a basic definition can be given as follows. 'Discourse,' as a mass noun only, and in its rather strict linguistic sense, refers to *connected* speech or writing occurring at suprasentential levels (at levels greater than the single sentence). Harris (1952) pioneered this approach to discourse, arguing that the methods of formal linguistics could be used to understand how sentences are connected, and not simply the formal structure which exists *within* the sentence itself. While Harris used invented data and attempted to find the formal structural properties of connected speech, this is now atypical—and not essential to Harris's definition of 'discourse.' Most discourse analysts these days (possibly beginning with Mitchell 1957) prefer to work with naturally occurring data (actual talk, actual texts) and to pursue the local–contextual features and social functions of them rather than their purely 'linguistic' (or systemic) properties. In this sense, a focus on discourse entails a shift in linguistics away from competence and the *langue* (the language system) and towards performance and *paroles* (actual speech events) (see *Saussurean Tradition and Sociolinguistics*).

However, the above definition is only an ideal type. There are many variations upon it and some discourse analysts would totally disagree with it (Frawley 1987). In what follows, after a brief look at the history of discourse and its analysis, there is an outline of, arguably, the three main approaches to it in contemporary scholarship: the formal linguistic approach (discourse as text), the empirical sociological approach (discourse as conversation), and the critical approach (discourses as power/knowledge).

Note, then, that it is in the last domain, associated with critical history and sociology, that we find the term '*a* discourse' most commonly used, referring to the nexus between bodies of historically volatile disciplinary knowledge and specific linguistic usages at social-institutional sites (hospitals, prisons, and schools, for example). However, the two terms ('discourse' and 'a discourse') are often used as proxies for one another, especially in the adjectival form 'discursive' which can refer to both domains. In some definitions the two are conflated:

> [Discourse] is a domain of language use, structured as a unity by common assumptions. There may be competing discourses, and discourses will change over time. For example, M. Foucault ... describes the existence of discourses of madness ... which have changed over the centuries. He also suggests that there may well be similarities between discourses at any time. The discourse of political economy in the eighteenth and nineteenth centuries, for instance, takes the same *form* as that of natural history.
>
> (Abercrombie et al. 1984: 70)

2. History and Diversity of the Term(s)

As van Dijk (1985a) points out, our modern linguistic conception of discourse (as language use) owes much to the ancient distinction between grammar and rhetoric. Grammarians explored the possibilities a language can offer as a 'calculus' for representing the world, and were concerned with correctness of usage. By contrast, rhetoricians focused upon practical uses of speech and writing as means of social and political persuasion. Grammar was akin to a reductive science, while rhetoric was more of an applied art. Although the ancient Greeks took both disciplines to be 'prescriptive,' modern linguists and sociologists are clearly more 'descriptive' in their approach; though it can still be useful to distinguish between language and discourse in terms of grammar, on the one hand, and rhetoric, on the other, as topics for that description. Continuing with van Dijk's brief history: after revivals of rhetoric in the middle ages and the seventeenth and eighteenth centuries, by the nineteenth and twentieth centuries, and particularly under the influence of Saussure, linguistics proper came to dominate the field of language study. Consequently attention was concentrated on modern versions of grammar: namely, formal properties of the language system.

However, the study of discourse has never been entirely neglected. Such early twentieth-century schools as the Russian Formalists continued alternative ('rheorical') traditions, focusing on textual discourse (especially folktales (Propp 1958)) rather than on the standard linguistic categories of phonology, morphology, syntax, and semantics for their own sake. In addition, French structuralism and

semiotics, in particular the early Barthes (1967), extended Saussure's original conception of the verbal language system to include forms of communication such as the fashion and food systems.

In this sense, the study of discourse (as language use) can be broadly and roughly associated with applied linguistics and particularly with the area of it which is now called 'pragmatics.' Indeed, sometimes the terms 'pragmatics' and 'discourse analysis' are used interchangeably (Levinson 1983)—even though the former term can also have a more technical meaning: the study of how speech acts (Austin 1975) are used in concrete social settings (see *Pragmatics and Sociolinguistics*). However pragmatics, considered broadly *as* discourse analysis, appears to have the following ideal-typical features: (a) it criticizes the idea that whole languages are exclusively formal grammatical sentence systems by proposing to examine actual contexts of language-in-use; (b) it construes language as primarily discourse(s)—as heterogeneous social actions in the first place rather than, say, as an innate property of the human mind which is merely put into social action or 'performed'; (c) it considers language to be produced and analyzable only in terms of the connection between utterances (writing and speech events) rather than in terms of single sentences; (d) it favors (though it does not exclusively use) naturally occurring rather than elicited or invented data. These data are typically transcripts of talk by more than a single speaker made from audio or video recordings; or else texts such as newspaper reports which would have been produced and consumed by social actors even if the analyst had no interest in them.

Not surprisingly, then, disciplines outside linguistics have laid claim to discourse as their proper object. These would include anthropology (Pike 1967), social psychology (Argyle 1969), artificial intelligence studies (Schank 1975), literary criticism and theory (Frow 1986), philosophy (Searle et al. 1980) and, particularly, sociology (Schenkein 1978). However, as yet, no single approach to discourse has emerged as dominant. And despite a number of textbooks and handbooks (van Dijk 1985b, Brown and Yule 1983), critics of very different persuasions seem to be convinced that no interdisciplinary synthesis has yet emerged (Stalpers 1988, Frawley 1987). Indeed, some have argued that a single, integrated and monolithic approach is actually less satisfactory than a piecemeal and multitheoretical approach (McHoul and Luke 1989).

Given the diversity of the field and the contestability of the above ideal-type criteria for discourse and its analysis, we must now examine how discourse has been analyzed and understood in the three major approaches already mentioned: the formal, the empirical, and the critical. Each is, in itself, multidisciplinary. Each has its own tensions, controversies, and contradictions; and each has occasionally been put into contention and/or synthesis with at least one of the other two. But each is sufficiently different from the others to offer a preliminary definitional scaffolding.

3. The Formal Approach

What can be called the 'formal approach' to discourse tends, by and large, to construe discourse as text. It is the most direct descendant of Harris (1952) and Mitchell (1957). Like Harris, it continues to have faith in formal linguistic methods of analysis. Like Mitchell, it moves in the direction of social functions and naturally occurring samples. It thus overlaps the equally diverse domains of sociolinguistics (Giglioli 1982) and the ethnography of communication (Gumperz and Hymes 1972). In the form of text linguistics (including text grammars), it has a precursor in the Russian Formalist school which, in its turn, via French structuralism (Saussure, Lévi-Strauss, and the early Barthes), connects this approach to structuralism in general and, perhaps, to the post-structuralist approach to discourse of Foucault, a principal theorist of the critical school.

However, via the systemic functionalism of Halliday (1973) and, more especially, via the extension of Halliday into social semiotics and critical linguistics by such analysts as Hodge and Kress (1988), the formal approach also connects with empirical sociological approaches to discourse. 'Critical linguistics,' in this sense, is perhaps currently at the forefront of discourse analysis—a major contender for being the dominant paradigm. For although it does not always pick up on the work of the French critical discourse theorists (such as Foucault)—though see Fairclough (1989)—it promises a unique amalgam of a firm linguistic base (Hallidayan systemic functionalism) with an interest in actual rather than invented texts and an attempt to 'read' those texts as socially classed, gendered, and historically located. In some of its more directly political modes, it has begun to contribute to feminist theory and practice (Threadgold 1988) by challenging linguistically naive critiques of, for example, the gendering of pronouns (Spender 1980) and arguing that discourse analysis must look not at how a language in general is gendered but at how gender-differential forms of access to particular discursive registers and genres have become normal and dominant through complex historical processes.

In addition, some other analysts have begun to extend formalist methods to examine how discourses are 'owned' in terms of social class and ethnic identity. Mey (1985), for example, has looked at instructional texts in German for Turkish 'guest'-workers in terms of the subset of that natural language (the particular discourses within it) which the workers are permitted to command such that they

135

can be and become economically efficient without having full access to the cultural and linguistic environment in which their labor occurs and to which it contributes by reproducing materially crucial infrastructures.

However, these critical and political uses of formal linguistic methods are only one side of the coin. At another extreme, the formalist approach is mechanistic—attempting as it does to read off quite general discursive norms from imagined or invented texts, as though discourse were less of a social phenomenon and more of a formal system in its own right, requiring a relatively narrow linguistic description. As with certain kinds of speech act theory, this extreme formalism appears to hold to a vaguely pragmatized notion of competence—as if '*paroles*' (performed utterances) had a discursive system to them which was other than (but formally like) the '*langue*' (the language system).

A classic instance of this is the work of Grice (1975) who is often associated with speech act theory and who attempted to generalize from how he thought conversations operated in order to list a number of 'postulates' for conversational practice. In this sense, he believed he was describing a kind of practical linguistic universal: conversational competence. The postulates (which boil down to 'be polite,' 'be economical' and so on) are by no means universally found in actual conversations. Moreover they seem to give an ideal-rational version of socially pragmatic events so that it seems virtually irrelevant that the objects of the analysis (conversations) are both suprasentential and constitute a form of social action.

A more recent heir to the formalist approach has been text linguistics (TL). The term was first used by Coseriu (1955–56) and taken up by Weinrich (1967). But it was internationally pioneered by van Dijk (1972) and later developed by de Beaugrande (1980, 1984)—though van Dijk has, to some extent, recast TL as discourse analysis, thus departing fundamentally from the original TL project. That project owes much to the subdisciplines of poetics, stylistics, and narratology and is one of the many instances where discourse analysis shows its attachment to and development from formal literary interests. TL's goal is to be able to read off, for example, literary or 'social' effects from the strictly linguistic level of texts. TL analysts have, therefore, attempted to ask (at one extreme) 'what kind of speech act is a poem?' (Levin 1976) and (at the other) how phonological parallelism operates in the advertising of cheap motels (de Beaugrande 1985: 54–61). Thus, in its most formal mode, TL attaches itself to the logical/philosophical tradition of Searle and Austin and, in its most contextualized mode, it joins contemporary literary theory in becoming highly piecemeal in its conception of textual meaning. However, it should be

remembered that even in this latter form, TL retains Harris's initial interest in fairly traditional analytic versions of language and can often be no more than formal linguistics applied to noninvented data.

Thus we find attempts to link intonation directly with semantics (Johns-Lewis 1986); analyses which attempt to read off discursive coherence at the morphological level (Dressler 1985); similar attempts to locate discursive cohesion at the lexical level (Petöfi 1985); re-readings of formal semantics in terms of discursive function (van Dijk and Kintsch 1983); and studies which use readers' protocols as the basis for analyzing discourse comprehension (Ericsson and Simon 1984). What is lacking from such studies is, however, a critical theory of discourse as social action. In its place there is a matching procedure between quite separate linguistic and discursive levels, with the linguistic construed in terms of well-tried formal concepts and the discursive in terms of suprasentential concepts such as coherence, cohesion, and function. At best, this work contributes to a micrological ethnography of how some actual texts may operate in specific settings. At worst, it is probably a misnomer to call it 'discourse analysis' at all; Brown and Yule (1983) being a case in point.

In this respect, even more peripheral uses of the term 'discourse' have occurred in other fields. For example, the term is frequently used in cognitive psychological analyses of text processing (Freedle 1977). Such studies are almost uniquely confined to psychological interests, subsuming discourse under a concept of text, and text under a traditional psychological conception of memory. Insofar as they assume doggedly consensus models of social interaction (if they refer to the social at all) and since they are more interested in cognitive processing than material practice, their use of the term 'discourse' is probably marginal to pragmatic conceptions of discourse. Indeed, Coulter (1983) has offered a thorough-going critique here, precisely in terms of psychological naivety about actual speech situations.

A few analysts who have been classed as social psychologists have, it is true, examined how social interaction is managed through discourse (Argyle 1969). But otherwise, because of their insistence on understanding 'discourse' in terms of individuated cognition and 'behavior,' social psychological approaches are as yet marginal to discourse analytic interests. When the central focus of analysis is on, for example, personality rather than social practice, it is probably true to say that one is not actually dealing with anything that most social scientists (including linguists) would recognize as discourse. It may be fascinating to find that personality (measured by standard technical indices) varies according to social contexts; or that social contexts are 'influenced' by the 'personalities' which contribute to them. But the

fact that either is a function of the other would seem to promote a technical–correlational mode of analysis, essentially removed from both linguistic and sociopolitical relevances.

Moreover, very little psychological work on discourse has paid attention to the precise detail of actual materials, recorded in the field; rather it has preferred elicited 'responses' or completely contrived data (Edmonson 1981). Elicitation suggests quantification (Allen and Guy 1974) or controlled 'scientific' experimentation; while contriving data suggests that the object of analysis is a unitary single language rather than local domains of discourse. To examine discourse or discourse*s*, as such, would seem to mean avoiding or negating both of these extremes.

4. The Empirical Approach

The 'empirical approach' largely consists of sociological forms of analysis which have taken 'discourse' to mean human conversation. Yet its object has been not merely the formal description of conversational 'texts' but also the commonsense knowledges at the basis of conversational rules and procedures. While several approaches could be dealt with in depth—for example the Birmingham school (Sinclair and Coulthard 1975)—arguably the most fruitful work to date has been accomplished in the area of conversation analysis (CA), pioneered by Sacks and based on the ethnomethodological approach to sociology of Garfinkel (1967) (see *Conversation Analysis*; *Sacks, Harvey*).

Garfinkel offers a critique of American structural functionalism, based as it is in the assumptions of Durkheim. Whereas Durkheim took pre-existing social facts to be sociology's proper object of inquiry, Garfinkel (1974) coined the term 'ethnomethodology' to refer to an interest in how social members (ethnos) rely upon a relatively stable corpus of general methods for the accomplishment of social facts. Although the approach stems from Schutz's (1962) insight—roughly, that social objects are preinterpreted by members and are therefore essentially different from natural objects—Garfinkel disagreed with Schutz as to how social objects are constituted. Schutz favored a phenomenological position, considering social action to be a function of consciousness and locating the bases of action in a set of anthropological constants (such as the assumption of the 'reciprocity of perspectives'); whereas Garfinkel preferred to think of social action as an entirely technical or methodic accomplishment on the part of social members, taking place audially and visually in actual, material circumstances.

On this basis, Sacks asked how conversations (as social objects) are accomplished by their participants via a set of relatively stable techniques. His seminal work, with his colleagues Schegloff and Jefferson (Sacks et al. 1974), on turn-taking and on correction (Schegloff et al. 1977) in conversation are the field's classics. While some commentators (Frawley 1987) have argued that Sacks's main motivation was to find 'deep' or underlying social competences in the form of cognitive rules, it is also possible to argue that, throughout his work, Sacks was devoted to an approach which begins with the analytic object itself. Thus most CA work begins with a corpus of materials, rather than theoreticist arguments about the mind, cognition, or human nature.

CA's typical materials consist of transcriptions of conversations which would have taken place in (and as) actual social settings, regardless of the analyst's interest in them. If, as Garfinkel argues, society is accomplished audio-visually (or 'scenically'), then videotapes and their transcripts will (at least to some degree) provide reliable representations of what goes on in (and as) society. The analytic point is then to find regular ways in which particular conversational phenomena are routinely accomplished—across a variety of occasions—by a meticulous inspection of conversational 'texts.' To this extent, CA may be thought of as a poetics of ordinary talk—one which is empirically rather than theoretically grounded.

At the sociological 'end' of things, CA is less interested in correlating official statistics on, say, suicide with other social variables (race, religion, ethnicity, gender, and so on) than in understanding, in this case, how persons routinely, in actual cases of interaction, represent the condition of, say, 'having no one to turn to' (Sacks 1967). Rather than collect statistics in classical Durkheimian mode, the conversation analyst would collect calls to counsellors and suicide prevention centers and inspect them (as Sacks did) for regular features—for example how callers refer to particular categories of social members (family, friends, professionals, etc.) in terms of the temporal ordering of their availability and candidature as 'someone to turn to,' such that not just any person can be turned to in just any sequence, thereby establishing the eventual category of 'having no one to turn to' as the product of highly organized social affairs. In this way, a sociological understanding of how practical discourses on suicide are accomplished can be built up. So rather than take suicide as a given social-structural phenomenon, CA looks instead at how practical social competences (methods) are able to produce effects (such as 'suicides') which are read, after the fact, by traditional sociology as structural. Yet, insofar as come CA does indeed try to locate general forms of conversational competence (while other CA work is entirely piecemeal and occasion-specific), it can sometimes be mistaken for a strictly formalist inquiry into discourse. Nevertheless, even a brief look at the history and development of the approach lends credence to the view that it is, in fact, empirically rather than formalistically motivated.

In its earliest forms, CA was interested in particular kinds of conversational sequence, and especially in the ways in which conversational utterances are accomplished in pairs such as QUESTION + ANSWER. In an early study of telephone calls, Schegloff (1968) showed how opening turns consist of specific paired slots such that, when a second pair-part is absent, both the caller and the person being called can hear that a structural requirement of phone calls has been breached and may be in need of repair. This interest in pairs led Schegloff and Sacks (1973) to investigate how conversational openings and closings are accomplished through collaborative work on paired turns by each participant. Accordingly, this interest in sequential requirements and options led CA to investigate conversational turn-taking rules generally (Sacks et al. 1974), and to ask how conversational repairs are carried out in terms of a structural preference for self- versus other-correction (Schegloff et al. 1977; for 'preference' see below).

Heritage (1984) gives a comprehensive account of the variety of topics analyzed in CA. He divides the field into six parts, each of which will be dealt with separately below.

Picking up on the work of Schegloff et al. (1977), analyses of 'preference organization' use the term 'preference' not in a psychological sense but in one which stresses the discursive and institutional aspects of certain types of utterance. Some sequences are routine or 'unmarked' (for example, OFFER + ACCEPTANCE); others can require delays, qualifications, or mitigations (for example, OFFER + REJECTION). The first types are referred to as 'preferreds'; the second as 'dispreferreds' (Levinson 1983).

A second development noted by Heritage is the analysis of topic organization. In particular a number of analyses have been made of how topics move across boundaries. Button and Casey (1982) have shown how topic boundaries are worked by participants, in distinct but cooperative ways. They suggest a set of 'boundary procedure types,' each with a different suitability for specific kinds of conversational environment. As Heritage notes, this aspect of CA is still under development but it may yet prove to be an alternative to traditional proposition-based approaches to topic (Brown and Yule 1983: 106–14).

The third development mentioned by Heritage is the analysis of nonlexical items: particularly 'response tokens' ('mm, hm,' 'oh,' and so on) and laughter. The first of these reflects CA's propensity to focus upon sequential aspects of ordinary talk: that is, there are relatively precise slots where response tokens may occur, for example at and around the termination *points* of turn-constructional units (points where a speaker's turn may come to an end—though speakers can indeed 'speak through' them). To this extent, response tokens are positioned at actual ends of turns, or else at audibly 'end-appropriate' slots within the turn (Schegloff 1982). The analysis of laughter shows how CA treats discourse in its particularity; no topic can be taken off the agenda, *a priori*, simply because it appears unimportant from standard linguistic or sociological points of view. Some psychologists have assumed that 'random laughter is obviously pathological' (Frawley 1987: 382), directly against Jefferson's (1985) CA-informed insistence that it is a sequential and far-from-random discursive event. Indeed, Jefferson's work has begun to show just how surprisingly consistent the sequential positioning of laughter in conversation can be. In this respect, CA can begin to claim that what some disciplines write off, preanalytically, as 'random' or 'pathological' are in fact organized social practices and outcomes, brought off publicly and materially by social members in collaborative ways.

Another move in CA has been towards the analysis of nonvocal aspects of discourse (gesture, gaze, etc.) in terms of their position within conversational organization as a whole. Goodwin (1981), for example, lays particular stress on how gaze operates both during (and as an integral part of) exchanges of speakership and hearership. It appears that requesting and achieving gazes and taking and exchanging turns can be highly related interactional activities.

A further extension of CA—and one which offers some possible connections with critical modes of discourse analysis—has been its move away from 'conversation' as such and towards other modes of discourse that occur within specific institutional settings such as schools (McHoul 1978) and courtrooms (Atkinson and Drew 1979). Unlike conversations, discourse in these locations has a somewhat more 'preallocated' character to its turn-taking procedures so that not all participants have identical rights and obligations to speak or listen. It is a matter of some conjecture as to whether this kind of analysis will stretch sufficiently to dovetail with critical discourse analyses of power. However, it appears to be the case that CA has something *to offer more critical work* in the sense that it can locate 'disparities' and 'inequities' with some analytic precision, in actual conversations, and without resort to mere theoretical speculation (Clegg 1975). For example: it does not require the assumption that 'power' *is simply an inherent property of particular* social roles or positions.

Finally, Heritage suggests that some work of the 1980s, such as Jefferson's (1980a, 1980b) on troubles talk, has moved CA away from its interest in specific conversational episodes and slots (turn-transition points, openings and closings, etc.) *and towards the analysis of extended episodes of talk.* In her analyses, Jefferson shows how the telling of troubles and anxieties is negotiated between participants in six stages: approach, announcement, exposition,

'work-up,' 'close implicature,' and exit. Whether this might lend microprecision to critical analyses of the 'confessional' (Foucault 1979)—a central social institution by which surveillance of the interiority of subjects is accomplished—is an exciting avenue for further research on the boundary between these two approaches to discourse.

In any case, Heritage's location of recent developments in CA suggests that it is becoming a much more extensive approach to discourse than is often assumed from a limited inspection of the classics on turn-taking and Q–A pairs (see above). And in this respect, a development Heritage does not describe is the growing body of CA-inspired analyses of written texts—fiction, newspaper articles, etc. (Chua 1979; Morrison 1981). Relatedly: while CA 'proper' continues to have a largely technical interest in the sequential accomplishment of linguistic–discursive features, quite a number of CA-trained analysts are now moving towards the possibility of using CA's undoubted analytic precision to support (or indeed reject) more speculative but politically committed moves in other branches of institutional discourse analysis.

Emmison (1989), for example, has looked at how CA might shed light upon the authenticity of a 'conversation' which was in doubt during a major trial: where a suspect may (or may not) have been framed by the police on the basis of a taped talk between an officer and an informant. Hartland (1989) has analyzed trial transcripts as discursive events produced by and for pro-state procedures. He speculates on the idea that what traditional sociologists refer to as 'the state' may itself be produced, literally, in and by such discursive events, and that CA may therefore have something to offer critical theories and analyses of the state. McHoul (1986) has applied CA to the analysis of a university lecture as a highly localized contribution to the policing and enforcement of dominant modes of sexual morality and training. In addition, Smith (1987) has used ethnomethodological and CA insights into discursive practices (in conjunction with other sociological approaches) to generate a unique methodology for feminist sociology.

In such ways, CA, while remaining committed to actual rather than invented materials, and while insisting on analytic precision rather than ungrounded theorizations of discourse, is already beginning to extend its boundaries. While it already overlaps formal-linguistic approaches to discourse, it is now coming, albeit slowly, to some preliminary points of contact with critical approaches. It is to the latter that we now turn.

5. The Critical Approach

As noted above, continental discourse theorists such as Foucault, Lyotard, Donzelot, Pêcheux, and De Certeau tend to use the term 'discourse' to refer to relatively well-bounded areas of social knowledge. So, at any given historical conjuncture, it is only possible to write, speak, or think about a given social object (madness, for example) in specific ways and not others. '*A* discourse' would then be whatever constrains—but also enables—writing, speaking, and thinking within such specific historical limits. Thus while a discourse can be thought of as linguistic in one sense, it also has to be treated in terms of the conditions of possibility of knowing a specific social object.

This type of 'discourse theory' may be less well-known in Anglophone linguistics circles than formal and empirical approaches. It originated in continental, largely French, philosophical traditions and has its most cogent application (not in relation to language systems but) in relation to the history of ideas O'Sullivan et al. (1983: 72–3) argue that it originated with the early structuralists' opposition to 'inherited habits of thought and analysis' which assumed that social and cultural 'objects' existed in the 'real world.' The structuralists tried to show that, on the contrary, these objects exist only 'as products, not sources, of . . . signification.' But this structuralist and eventually poststructuralist position on discourse does not mean that 'anything goes,' that we can make the world into anything we want simply by speaking, writing, or thinking in a certain way (cf. Macdonell 1986). On the contrary, it is intended as a critique of individualism and idealism. For what an individual, a group, or a society as a whole, can imagine (let alone put into practice) is both permitted and constrained by the discursive possibilities at its disposal.

As Wittgenstein (1968) put it, 'to imagine a language means to imagine a form of life.' Thus 'the world' and our consciousness of it are discursive products; but, at the same time, discourse is a material condition which enables and constrains the socially productive 'imagination.' These conditions can therefore be referred to as 'discourses' or 'discursive conditions of possibility.' Moreover, as Voloshinov (1973) first showed, such discourses can come into contention and struggle. And this would include analytic discourses themselves; leaving them with (not so much a 'methodological' problem as) a problem of intervention and strategy.

Examples of this kind of interventional critical discourse analysis are to be found in the work of the anthropologist Eric Michaels (e.g., 1987) and the coproductions of Australian Aborigines with discourse analysts (e.g., Benterrak et al. 1984) which owe as much to contemporary literary theory as they do to poststructuralist discourse theory. At the same time, such interventions cannot afford to neglect a firm theoretical basis and it is to this that we now turn by looking at how Foucault characterized the

139

'components' of discourse. The focus here is on Foucault's (see *Foucault, Michel*) own contribution to discourse theory, neglecting the many offshoots and applications of his work in such fields as the history of statistics (Hacking 1981, 1982), the family (Donzelot 1980), legal discourse (Wickham 1987), literary discourse (Williamson 1989), feminism (de Lauretis 1984), photography (Tagg 1988), the body (Turner 1984), and pedagogy (Luke 1989).

Foucault has argued that formal and empirical approaches have tended to work on the side of the enunciation (*énonciation*) of discourse. Such a narrow focus can only include the surface of language use, the ways and means by which concepts and meanings are spoken or written. In place of this emphasis, Foucault (1972) proposes to look at discourse*s* at the level of the enounced (*énoncé*) or, as his translators put it, the 'statement.' Rethinking his own earlier work (Foucault 1970) on the historical emergence of the discourses on life, labor, and language (eventually, biology, economics, and general linguistics), Foucault (1972: 80) considers his failure to specify the terms 'discourse' and 'statement':

> ... instead of gradually reducing the rather fluctuating meaning of the word 'discourse,' I believe that I have in fact added to its meanings: treating it sometimes as the general domain of all statements, sometimes as an individualizable group of statements, and sometimes as a regulated practice that accounts for a certain number of statements; and have I not allowed this same word 'discourse,' which should have served as a boundary around the term 'statement,' to vary as I shifted my analysis or its point of application, as the statement itself faded from view?

In order to clear up the confusion, Foucault asks whether it is possible to think of the statement as a unit of (a) discourse. If so, it is then necessary to ask what kind of unit it is. For example, could it be the same as a proposition, a sentence or a speech act? Let us take these in order.

A statement cannot be identical with a proposition. To cite Foucault's (1972: 81) own example, 'No one heard' and 'It is true that no one heard' have identical propositional contents but may constitute two different statements. If each were to occur as the first line of a novel, he goes on, they would involve different orders of narration. The first might be 'an observation made either by the author, or by a character' while the second 'can only be in a group of statements constituting an interior monologue, a silent discussion with oneself, or a fragment of dialogue, a group of questions or answers' (1972: 81). Thus, Foucault's first criterion for a statement is that it should be responsive to what Pêcheux (1975) calls 'functioning.' Propositional content is, at least traditionally, thought to transcend local specifics of usage. Unlike propositions, statements—as

components of discursive formations—have to be thought of primarily as functional units.

A statement cannot be identical with a sentence. This is not simply because truncated 'sentences'—such as 'Absolutely!'—can carry the force of statements. This objection would be trivial since even formalist approaches acknowledge that such truncations can count as sentences. Further: since the sentence itself is so poorly defined, it will never be possible to pronounce decisively on its equivalence or otherwise with the statement. However, it is possible to say that certain word groupings which are clearly not sentences do carry the force of statements. Foucault's (1972: 82) example is the paradigm of the verb *amare: amo, amas, amat* .... This is a 'statement of the different personal inflections of the ... verb.' Thus classificatory schema, tables, taxonomies, etc., though rarely expressed in sentential form, can carry the force of statements. And more importantly, perhaps, they show clearly how coherent groupings of statements (discursive formations) act as constraints upon, and enablers of, specific knowledges. Just as the statement is not propositional, neither is it characterized by its grammatical form, for expressions which do not use verbal language may count as statements: 'a graph, a growth curve, an age pyramid, a distribution cloud ...' (1972: 82) may all be statements but have no clear grammatical form unless one is to stretch the term 'grammar' into metaphorical domains beyond its normal confines.

A statement cannot be identical with a speech act. This is because some but not all speech acts require more than a single statement in order to be 'felicitous' (Austin 1975). Hence, 'empirical' equivalences between (some) speech acts and (some) statements are merely coincidental. Speech act theorists may see equivalence between the utterance 'I promise' (said as a proposal of marriage within the discourse of medieval romance) and 'I promise' (said by a character in a modern soap opera as an agreement to meet for lunch). But each is a different statement, being located within totally different social 'technologies' and historically formed discursive practices. Each produces individual human subjects or 'actors' in distinct ways. Each (re)creates and maintains different sociopolitical institutions.

Thus a statement is not strictly a unit at all in the sense that the proposition, the sentence, and the speech act are. Instead, it is a 'function that operates vertically in relation to these various units, and which enables one to say of a series of signs whether or not they are present in it' (Foucault 1972: 86). It is 'not itself a unit, but a function that cuts across a domain of structures and possible unities, and which reveals them, with concrete contents, in time and space' (1972: 87). Therefore, statements are best understood in terms of the rules which govern their functioning.

But these rules are no longer susceptible to a general theory of language. Statements and their rules are neither purely linguistic nor purely material but exist in, and as, the nexus between these two domains. In order to analyze or describe rules, one must always turn to specific historical conditions of usage—to the piecemeal, the local, and the contingent. For events, no matter how specific, cannot happen just anyhow. They must happen according to certain constraints, rules, or conditions of possibility; according, that is, to 'power relations' in Foucault's sense.

For Foucault, 'power' is not equivalent to traditional sociopolitical concepts which go by the same name, since it is never devoid of discourse. Discourse is not a mere effect or end-product of a prediscursive 'power.' In this sense, power is not 'owned' by some privileged group and exercised 'simply as an obligation or a prohibition on those who "do not have it"' (Foucault 1977: 27).

> Power is everywhere; not because it embraces everything but because it comes from everywhere .... Power comes from below; that is there is no binary and all-encompassing opposition between ruler and ruled at the root of power relations, and serving as a general matrix—no such duality extending from the top down and reacting on more and more limited groups to the very depths of the social body. One must suppose rather that the manifold relations of force that take shape and come into play in the machinery of production, in families, limited groups and institutions, are the basis for wide-ranging effects of cleavage that run through the social body as a whole.
>
> (Foucault 1979: 93–4)

Yet, as Eco (1986: 244) has it, this radically diversified conception of power is by no means 'unlinguistic.' Power and discourse not only constitute one another reflexively but also:

> [Foucault's] ... image of power closely recalls the idea of the system that linguists call *the given language*. The given language is, true, coercive (it forbids me to say 'I are him,' under pain of being incomprehensible), but its coercion doesn't derive from an individual decision, or from some center that sends out rules in all directions: It is a social product, it originates as a constrictive apparatus precisely through general assent .... I'm not sure we can say that a given language is a device of power ... but it is surely a model of power.
>
> (Italics added)

Thus the linguistic system (the '*langue*') is not the sovereign source of discourses which are its mere effects. On the contrary, the linguistic system is just one instance (or 'model') of power considered as a diverse, piecemeal, local, and pragmatic/discursive set of relations of force. Hence, methodologically speaking, these relations cannot be known in advance from some grand theoretical 'prediction.' Only determinate (archaeological) investigations can

specify them. And possibly, as Hunter (1988) has pointed out, even the *Archaeology of Knowledge* may already be too generalist in this respect.

Returning to statements then: they are best approached not as single items but in terms of the systems or 'archives' of which they form a part. Hence what can be said or not said about a specific 'object' is neither absolutely fixed, nor is it open to complete indeterminacy in any actual case. For:

> the archive ... determines that all these things said do not accumulate endlessly in an amorphous mass, nor are they inscribed in an unbroken linearity, nor do they disappear at the mercy of chance external accidents; but they are grouped together in distinct figures, composed together in accordance with multiple relations, maintained or blurred in accordance with specific regularities.
>
> (Foucault 1972: 128)

Effectively then, the statement is a sociohistorical function rather than a strictly linguistic one. Yet (and this is probably Foucault's contribution to the neolinguistic study of discourse) the statement can still be located in talk and texts, thereby allowing us a method of working from 'empirical' statement to 'systemic' archive and thence to a sense of the double uniqueness-and-continuity of social histories of thought, knowledge, and power. In an interview, Foucault (1981) called this method of tracing the systematic (archival) properties of piecemeal and local affairs 'eventalization'—the heuristic of turning either documents or 'grand' historical movements into concrete events. It is no accident, then, that he refers to the archive as 'the very root of the statement-event' (1972: 129).

However, the concept of the discursive archive cannot be a simple replacement for concepts like 'system,' '*langue*' and so on. Rather, analyses of an archive as a condition of enunciation, or of its stable system of functioning (at specific conjunctures), must be taken hand-in-hand with analyses of its historical flux, of 'the general system of the formation and transformation of statements' (1972: 130). In this sense 'archive' is a much more mobile and fluid term than the relatively fixed concept of 'episteme,' used in the earlier *Order of Things* (1970). The concept 'deprives us of our continuities' (1972: 131) and establishes the fact that human subjects are not firm and discrete (id)entities but are fragmented and changing sites across which the play of difference moves. The archive, more radically, 'establishes that we are difference, that our reason is the difference of discourses, our history the history of difference, ourselves the difference of masks' (1972: 131)—a position which Goffmanians (see *Goffman, Erving*) will readily identify with. The discipline which describes that radical formation of individual and historical subjectivity, Foucault (1972; 131) calls 'archaeology.' As an example of it, we could turn

to his and his students' analyses of the case of Pierre Rivière (Foucault 1978).

One way in which Foucauldian discourse analysis is critical is that it describes how social scientific and other disciplinary discourses repress more marginal, less dominant, forms of knowledge. In *I, Pierre Rivière* ... (1978), Foucault and his co-workers reproduce many of the original documents pertaining to the case of a multiple murderer caught in the contradictions between two official discourses on punishment, roughly those of the eighteenth and nineteenth centuries. Thus they are able to analyze a specific conjucture (via its archival trace) in which one system of statements on punishment comes to replace another. The earlier system is corporeal, involving as it does overt and ritualistic public punishment of individual bodies. The later one tries to control populations (rather than bodies). And it does this in a very different way: by putting them under constant watch, under a scientifically justified and controlled gaze. The first involves punishment by spectacle (public hangings, for example); the second involves punishment by surveillance, typified in Jeremy Bentham's panoptic prison designs (see Foucault 1977). Moreover, it should be noted as a methodological point that, in analyzing this particular case, Foucault shows the interrelations between at least two adjacent fields of discourse: the first comprising statements (events of punishment inscribed on bodies), the second comprising official discourses whose statements construct and circulate around acts of justice. These are two 'large groups of statements' (1972: 37) or discursive formations; but, as Foucault has pointed out elsewhere (1971), statements do not overdetermine the discursive formations which they form. Instead, discourses are regulated by 'adjacent fields' and practices. Hence any actual event (such as the Rivière case) requires an analysis in terms of adjacency; and hence the doubling of the discursive field in this case.

Rivière is trapped between the two; between the new public and panoptic discourse on punishment, and the old mode of spectacular retribution. The courts cannot decide whether to 'make an example' of him, after the moral techniques of the eighteenth century or whether to be 'humane' and condemn him to a life of continual surveillance. There was an effective crisis, at the time, over what was to count as the official discourse on punishment. The emergent scientific discourses of medicine and protopsychiatry had the same problems: did the theoretical object called 'monomania' actually exist? And if so, to what extent could its existence 'excuse' a multiple murder by replacing the individual with a 'disease' as the responsible agent? Likewise, as Foucault shows, popular discourses (such as journalism) were equally at odds over the issue, showing how discourses in adjacent fields can coincide to give the effect of

collusion or conspiracy where none exists. Insofar as Rivière is caught between these two moments of official (and popular) dispute on the best course of punishment, his own account is continually pressed back into the margins and cannot be heard in the open space of official discourse.

The problem then for the social sciences (for law, medicine, etc.) is to know how to treat, in both senses, Rivière's remarkable personal memoir of the murders. Because scientific discourses seek to 'explain' crime, the criminal's own discourse is reduced (by, for example, criminology) to the same status as the criminal conduct to be explained. It becomes, for example, a confession. And so it is interesting to trace Foucault's own discursive strategies in the Rivière text; because, for Foucault, to repeat a practice uncritically is to support it—and it would therefore seem contradictory were he to side with the disciplinary techniques of law, criminology, pathology, etc. For example, in his debate with the Maoists, recorded in *Power/Knowledge* (1980), Foucault argues that the strategy of setting up a court to try the police for their crimes constitutes merely a repetition of bourgeois forms of justice. The point is that a technique, whatever its 'content' or the class polarity of its content, is a bearer of power in itself. Critique consists in ceasing; in ceasing to repeat the scientific/official technique.

Clearly then, Foucault's treatment of the Rivière texts is not an 'analysis' in any sense that traditional linguistics could recognize. It shows rather than says how the operations of power worked at a particularly contradictory site. For to say those operations, even in the guise of a technical/analytic discourse, would be to continue to repress the alternative and marginal construction(s) of the murder (and the events prior to and after it) provided by Rivière himself. An upshot for critical/interventional discourse analysis might therefore be framed in terms of the following question: how can discourse analysis provide a place for the mad, the imprisoned, the marginalized, the cultural and political 'other' to speak or write without the appropriation of 'their' discourse by translation into the terms of apparently neutral (but in fact highly repressive) scientific/analytic discourses—including the discourses of formal linguistics and sociology?

To take just one case: what is the point of Labov (1982) saying, analytically, how the logic of 'non-standard' black English works—morphologically and syntactically—using the language of the academy, when, all along, the 'non-standard' discourse, by definition, has no clearly sanctioned possibility of being heard or written in the academy as an equal and alternative discourse? If discourse analysis is to be involved in political struggles—that is, in changing rather than simply describing social conditions of possibility—it may have to face the fact

that the 'disciplines of discourse,' as van Dijk (1985b) calls them, are, at the beginning of the twenty-first century, no more than discourses of discipline—armatures of dominant modes of social power. (At least, a discourse-theoretical investigation of much contemporary discourse analysis might show that, in a disciplinary sense, discourse analysis *is* official discourse, Burton and Carlen 1979.) A radical rethinking of the distinction between theory and practice, or between commentary and text, would appear to be a major priority in discourse analysis. The first domain (theory/commentary) would have to consider itself in terms other than those of mere analytic accuracy or scientific coherence and validity—thus using its insights into (supposedly) 'actual' discursive processes in order to facilitate discursive spaces for the second domain (practice/text) to be able to speak and write in, and on, its own terms.

Discourse in Cross-linguistic and Cross-cultural Contexts
M. Clyne

This article first differentiates between three types of cross-linguistic and cross-cultural situations. It then concentrates on communication between people with different first languages sharing one language which is their second or later language. The study of such communication is located within the discipline of linguistics. The main issues of research in this area are enumerated and the theoretical and practical value of such research and the methodology employed are discussed. An attempt is made to explore the role of underlying cultural value systems in determining cultural differences in communication patterns.

1. The Field

The term 'discourse' is used here to refer to continuous passages, whether oral or written, which extend beyond the sentence level.

Because of migration patterns, opportunities for travel, international teamwork projects, and greatly improved communication technologies, communication between people of different ethnolinguistic and cultural backgrounds is commonplace. Such communication may be between:

(a) people sharing two or more languages;

(b) people with different first languages sharing one language which is a second or later language for some or all of them;

(c) people not sharing any language or with both (all) having only a limited competence in a shared language.

In case (a), the context may be one such as a migration (or colonial) situation in which one language is replacing another. This situation will usually be characterized by the transference of rules, features, and meanings from L2 (the second language) to the original L1 (first language). For instance, Italian speakers in Australia will transfer the meaning of English 'factory' to similar-sounding *fattoria*, originally meaning 'farm' ('semantic transference'), and integrate English 'farm' into Italian (make it part of the Italian system) as *farma*

(phonologically integrated 'lexical transfer'). Some Dutch–English bilinguals in Australia generalize the SVO (subject–verb–object) word order as in English so that:

> Maar als wij *praten* in het Hollands, *ze verstaan* drommels goed.
> (But when we speak in Dutch, they understand damned well.)
> replaces
> Maar als wij in het Hollands *praten, verstaan ze* drommels goed
> ('Syntactic transference')

Communication in bilingual situations will also often be marked by 'code-switching.' A switch from one language to the other will be conditioned by a change of interlocutor or silent participant, a change of venue, a different role relationship with the interlocutor, a shift in domain (e.g., from home to work or school) or a variation in type of interaction (e.g., serious business to joke). It may be due to stylistic considerations, such as the inability to express something in as idiomatically adequate a way in the other language or the switch may become a symbolic part of the message, e.g., it may signal membership of the in-group.

In the bilingual discourse that develops in many immigrant families, where parents use L1 and the children respond in L2, where L2 = the national language of the immigration country, key words from either language will be inserted in discourse in the other language:

> Parent: Wenn du allein gehst.
> (if you are going on your own.)
> Child: But I'm not going *allein.*

In case (c) above, simplification will occur where both speakers have only a limited proficiency in the target language. This can lead to the use of a pidgin (e.g., Tok Pisin in New Guinea) in contact between speakers of more than two different languages. In contact situations between native and non-native

145

speakers, the former may employ a simplified register known as 'foreigner' talk (see *Foreigner Talk*). Nonverbal means of expression (e.g., gestures) will usually be employed to replace or supplement verbal ones even more than occurs between speakers with full competence in a common language. Like all communication rules, gestures will also vary in meaning and interpretation between cultures.

In case (b), people will generally transfer to their L2 discourse, communicative behavior and expectations from their first language and culture. This situation will provide the main focus of the present article.

The extension of the 'linguistic model' from purely grammatical considerations to include the social setting (e.g., in the works of Labov, Hymes, Gumperz) and to recognize variation as central has made it possible for wider issues of communication to be included in 'mainstream linguistics.' Four linguistic traditions have contributed particularly to the study of intercultural communication—ethnography of communication, linguistic pragmatics, discourse analysis, and conversational analysis. Also, some studies on cross-cultural discourse analysis involving cultures in developing nations have employed the tagmemics framework.

There are a number of ways in which discourse in cross-cultural contexts is examined. One is for speech acts, such as requests, complaints, and apologies, to be taken out of the discourse framework and their realization by mother-tongue speakers of different languages contrasted. An instance of such a project is the Cross-Cultural Speech Act Realization Project contrasting Australian English, Argentinian Spanish, Canadian French, German, and Israeli Hebrew (reported in Blum-Kulka et al. 1989; see also *Pragmatics and Sociolinguistics*). Another approach is to focus on the pragmatic rules of acquirers of a second (or later) language whose interlanguage contains instances of L1 interference, simplification, overcomplexity, hypercorrection, and overgeneralization (see Blum-Kulka and Kasper 1994). These two approaches sometimes overlap. The investigation of culture-specific rhetorical/textual patterns is conducted either in a contrastive framework or as an interlanguage analysis. In the kind of interactive situations which are being discussed in this article, the boundaries between pragmatic and discourse areas are fuzzy.

2. The Issues

People from kindred cultures (but not necessarily with the same L1 or from related L1 backgrounds) are likely to share expectations and patterns of communication. This is partly due to conversational inferences (deductions made about the intended meaning) being influenced by socio-cultural knowledge. The Vietnamese worker who, when asked by her Austrian superordinate at the start of a workplace communication in an Australian factory shortly before Easter: 'You have five days off. What are you going to do?' inferred that she was going to be laid off, was not able to make the right sociocultural connections. Where communicative expectations and patterns are not shared, experience or training can make people conscious of the range of communicative behavior and understand hidden implications. Without this knowledge a mismatch between communicative intention and communicative effect may lead to a communication breakdown. This can take the form of 'noncommunication,' where neither the intended message nor any other message is conveyed, or 'miscommunication,' where an unintended message is conveyed. The latter is more serious insofar as it can pass unnoticed by either party, thereby exacerbating ethnic and racial stereotypes and causing communication conflict in which dignity and trust are threatened. Miscommunication will not only be due to a lack of shared expectations and behavior. An anticipation of culture-specific communicative behavior may be inappropriate where interlocutors have adapted their communication patterns to those of the other group. This expectation of stereotypical patterns can lead to misinterpretation. In some cases, a clash between communicative behaviors can lead to communication conflict and friction between the parties.

Research has, until the early 1990s, been based largely on contrasts between the pragmatic rules (rules for performing speech acts, such as apologies, complaints, compliments, promises, requests) of English (British, American, or Australian) and those of a small number of other languages/cultures— German, Japanese, Polish, Hebrew, Spanish (see, for example, Blum-Kulka et al. 1989, Olesky 1989). A theoretical basis has yet to be firmly established. Some of the discussion is still anecdotal.

The main issues that have been raised are covered in the following sections.

2.1 Intercultural Variation in the Performance of Speech Acts

These are notably requests, complaints, and, to a lesser extent, apologies, promises, and greetings, and opening and closing routines. The following attempt at a typology starts with the seemingly most trivial whose absence or culturally inappropriate use can cause communication conflict as well as communication breakdown because they involve politeness and face. Contrasting formulaic routines include:

(a) The absence or presence of a rule—e.g., 'good appetite' or 'I am eating' said to mark the beginning of a meal. (The failure to observe this routine may be regarded as impolite by continental Europeans, Chinese, and Indonesians.)

(b) Formulas of completely different structures to perform a speech act—English 'excuse me' or Central European 'goodbye' for leave-taking at a restaurant table.

(c) Formulas of opposite structures employed to perform a speech act in different languages— e.g., English 'Is this seat taken?'/continental European 'Is this seat free?' This is even more likely to promote communication breakdown where speakers do not share a common language and their nods and head-shakes are based on different formulas.

(d) Formulas of corresponding structures employed to realize different speech acts—e.g., Australian English 'How are you (going)?' is often misinterpreted by Central Europeans as an inquiry about a person's well-being and the ensuing response considered by the Australian longwinded and unnecessary. 'Have you eaten already?' a greeting used by many Chinese and Southeast Asians when speaking English, can cause either miscommunication or noncommunication. It is not understood by the 'uninitiated' Australian, American, or English person and misinterpreted as an indirect invitation by some Central Europeans. The greeting 'Where are you going?' used in English by Singaporeans is misunderstood to be an inquiry by speakers of British, Australian, or American English.

(e) Formulas of corresponding structures used to realize speech acts with the opposite intention, e.g., 'Thank you' employed by English native speakers to denote the acceptance of an offer and by people from some continental European backgrounds to mean the rejection of the offer.

The distinction is often made between directness and indirectness. This encompasses the following dichotomies:

(a) *Direct* and *indirect* speech acts—e.g., the difference between the direct formulation, 'May I ask you to shut the door?' (or simply 'Shut the door') and the indirect, 'Don't you think it's rather cold in here?' Hinting rather than directly requesting a favor is considered to be polite in Southeast Asian cultures but sometimes devious when similar communication patterns are employed in communication with Britons or Australians or New Zealanders.

(b) The use of *downgraders*, such as 'well,' 'would you mind...?' conditional forms (could, would, should), impersonal constructions and agentless passives (e.g., It could be interpreted as..., This is seen to be), as opposed to *upgraders*, such as 'obviously,' 'absolutely.' 'I insist that ...'

(c) *Positive* vs. *negative politeness*—related to the notion of 'face' and developed in Brown and Levinson's (1987) pragmatic model based on degree of relative power, social distance, and the ranking of impositions in a particular culture. Negative politeness avoids conflicts through modesty, formality, and restraint (i.e., not imposing); whereas in positive politeness people draw closer by showing appreciation of one another, for instance, through solidarity strategies such as teasing or through what may be perceived as outspoken frankness. In different cultures, people lose face by apologizing, not apologizing, not apologizing in a particular way, or not successfully soliciting a reassurance (see *Politeness*).

It is surmised by some that communicative styles of certain cultures are more direct (given to 'overstatement'), the styles of others more indirect (given to 'understatement'). For instance, House and Kasper (1981) found that Germans showed a higher level of directness (more upgraders, less downgraders) than English people in the performance of requests and complaints. In the Cross-Cultural Speech Act Realization Project (Blum-Kulka et al. 1989: 62), downgraders in indirect requests were distributed according to the rank ordering—Australian English, Canadian French, Hebrew, and Argentinian Spanish, with the English speakers using twice as many downgraders as Canadian French and Hebrew speakers. The others make up for the lower incidence of downgraders by the increased use of please.

The directness-indirectness dichotomy has been challenged (e.g., by Wierzbicka 1991) on the grounds that these assumptions are based on selected aspects and have *relative* foundations. Anglo–American cultural style is direct when compared to Japanese but indirect when compared to Black American or Jewish–American style. Anglo–American style is direct in some ways, and more indirect in others. Within a particular supranational language there may be divergent tendencies not only in national cultures (American, British, Australian, Indian) but also in religious or ethnic subcultures. Wierzbicka has proposed a system of 'cultural scripts' based on a set of universal semantic principles, i.e., expressed in terms of basic elements such as: *I, you, want, don't, say, think, do, this, like this, good, bad.* She argues that the advantage of this approach is that it avoids arbitrariness in the formulation of absolutes and in the positioning of relatives. A counterargument is that the primitives may not be as universal as she assumes.

2.2 Intercultural Variation in Discourse Organization

This obtains in rules for the structure of telephone conversations, letters, school essays and academic

147

treatises, the conduct of meetings, consultations with professional people, and business transactions. This encompasses:

(a) turn-taking rules, i.e., who talks when in an interaction, how it is (or is not) possible to take over a turn from someone else, or prevent another person from appropriating your turn, and how long different interlocutors can talk for; and

(b) the various rules in written discourse and formal meetings which influence the degree of linear progression and symmetrical balance between propositions or segments of text or oral discourse.

English academic discourse has been found to be more linear and symmetrical than its German equivalent. This corresponds to variation in the dominant cultural expectations of good academic discourse and corresponding differences in the structure of meetings in English-speaking and German-speaking countries. Discourse in Japanese, Korean, Chinese and, to some extent, in the Indian traditions, tends to keep returning to the baseline. Arabic discourse marks parallels between elaborating or conflicting arguments. These organizational structures are to be found in both L1 and L2 discourse. Such differences can lead to difficulties in participating in democratic structures and problems in getting books, articles, and conference papers accepted or positively evaluated. Here too, ethnic stereotypes can result from discourse patterns that may seem to promote digressiveness or longwindedness when viewed from another culture.

In English, little creativity or special ingenuity is required for a conversation to flow from opening routines. In German, for instance, constraints are placed on the way in which communication can proceed between strangers unless they have established 'common ground.' Intercultural communication conflict may develop where one speaker considers the other to be either offensively forward or arrogantly uncooperative.

2.3 Intercultural Variation in Systems of Address

Some languages/cultures have more complex systems of address than others, involving different pronouns of address, verbal endings and titles according to status, relationship, and sometimes gender. Others (e.g., Australian English) do not mark these distinctions and also tend to prefer the general use of first names. Intercultural communication between people from cultures with different patterns of address may therefore engender problems of face, with interlocutors appearing too forward or too reserved. Speakers accustomed to marking status and special relationships through pronouns and titles will often find it difficult to interact in L1 with people with whom their common work language is English

where such relationships are less linguistically marked.

2.4 Intercultural Variation in Channel/Medium Rules

These rules indicate whether the communication situation requires face-to-face interaction, telephone or letter contact, or the completion of a form. For instance, in communication with bureaucracy, the telephone can be employed much more in English-speaking countries than in continental Europe where face-to-face communication (especially in Southern Europe) or form-completion (especially in Germany) is required. The choice of an inappropriate channel can limit access to information and/or success in communication with management or officialdom.

2.5 Linguistic Creativity Rules

These indicate the scope of 'language play'—rhymes, puns, limericks, verbal insults, and verbal irony. Such phenomena may be thought of as a 'luxury' layer, the province of writers, journalists, and cabaret writers and performers. They may simply not be understood in some cultures but they are a part of normal communicative behavior in others. So verbal insults from Turks, Hungarians, or Black Americans may be considered 'just offensive' by people from some other cultures, Central European irony may be completely missed by British or Anglo–Americans, and continental Europeans may simply not understand the punning of English speakers and its significance.

2.6 Small Talk

This obtains in the context of (casual) phatic communication to establish empathy between individuals, and it may be employed and understood quite differently across cultures (see *Phatic Communion*).

2.7 Intercultural Variation in Honorific Patterns

This is found especially in letters. In some cases these introduce an element of creativity into a conventional context. Some examples from the letters of Indian students:

> Expressions of deference—I beg to say (to state), I have the honor to intimate.
> Vocative of respect (to an 'ordinary person')—Respected Sir, Your Honour.
> Adjectival honorific—Your esteemed university, your respected school.

2.8 Some General Principles on the Above

Interaction with all these categories of rules is 'interlocutor-based' and 'domain-based.' *Who* is allowed to say this *to whom*? In what institutional contexts does this apply? The domain division may be stricter or less marked, according to culture, but all cultures have rules on how particular interactions

proceed (e.g., political interviews, university seminars), as well as constraints on their content. German conversation has been found to be characterized by a greater degree of directness than English conversation while German written academic discourse (in linguistics and sociology) contains more hedging devices than its English counterpart.

2.9 Intonation Patterns

These can influence not only the perception of the speaker's attitude but also the communicative intent (request or command). Gumperz (1977) gives the example of Indian and Pakistani cafeteria workers in Britian, whose use of falling intonation in the question 'Gravy?' was interpreted as unfriendly by their English customers who in the same situation would employ a rising intonation.

In another example from Indian English conversations, Gumperz et al. (1982) show that the intended meaning of a given utterance is, in fact, the inverse of the most straightforward prepositional interpretation. In the utterance:

> Building societies and the council have got no objection, *doesn't mean* that if a council house, council mortgage, you can still sell it.

The phrase 'doesn't mean' is used in this context, not to relate these clauses so much as to refer to assumptions expressed in the preceding dialogue. (On the surface this would appear to mean that one is not permitted to sell a council house; in fact the intended meaning is that one *is* free to sell it.) This is a further characteristic of Indian English likely to be misunderstood by speakers of other national varieties of English. Roberts et al. (1992) show how such variation can lead to discrimination in job interviews and in workplace communication.

2.10 Negotiation of Meaning and Resolution of Communication Breakdown

Where the interlocutors do not share common expectations of the interaction, the meaning needs to be negotiated, e.g., 'Do you mean you want a reason?' in response to a request for information followed by a long monologue on the part of the interlocutor. Where a communication breakdown has occurred, it needs to be resolved in a similar way. This is often done through slow, loud repetition or paraphrase depending largely on the level of competence of the speakers in the common language and their cultural backgrounds. South Asians are very likely to employ repetition. Even the response to the occurrence of communication breakdown varies across cultures in accordance with specific face-saving practices, for example,

(a) It may be ignored;
(b) It may be admitted according to culture-specific honorific rules;
(c) The other may be blamed for it;
(d) It may be 'laughed away.'

2.11 Some Intercultural Differences in Verbal Interaction

In a study of dyadic (workplace) communication in Australia (Clyne 1994) subject to individual, gender, and status differences, Central Europeans, South Asians, Latin Americans, and Filipinos tend to employ longer turns, to think aloud, and to interrupt one another's flow of speech—this can result in overlapping speech. East and Southeast Asians tend to employ shorter turns and long silences and not to expect small talk at work. Turn maintenance and appropriation tends to be achieved through an increase in speed and volume among people of Southern and Central European background and through a decrease in speed, rising intonation, and repetition among many of Southeast Asian origin. South Asians and some Central Europeans may excel in formal discourse or group discussions but not necessarily in small talk. Central and Southern Europeans will, on the whole, present an argument rather than a simple 'yes' or 'no' response, while comparable Southeast Asians will prefer the simple response which avoids an argument.

Among the effects of such variation in cross-cultural discourse are:

(a) Central Europeans' long apologies causing impatience to Anglo–Australian or Southeast Asian interlocutors with the Central Europeans, in turn, feeling rejected.
(b) In a complaint by a Central European, a surface request made for a reason ('Give me the reason') not accompanied by an opportunity for such a justification, leading to confusion on the part of Southeast Asians (see Sect. 2.10).
(c) Anglo–Australians' and Southern Europeans' rejection of clumsy attempts at small talk by a South Asian who himself takes over meetings through his domineering eloquence.
(d) Southeast Asians' inability to identify small talk in work communication.
(e) Central European women's competence at arguing with a Central European superordinate because they understand the hidden implications in his discourse and Southeast Asian women's inability to argue with him because they do not fathom out these implications.

For some people, silence in group situations is normal: for others it is intolerable as it causes alienation. Finns and Vietnamese immigrants in Australia are a cultural group who tend to observe long silences, especially in communication with strangers, while many Turks would expect to have long turns and not be interrupted. This has caused difficulties, for example, for Finnish business people

149

and Turkish migrant workers in Germany. In some cultures, such as Arabic, close proximity is a marker of friendliness but it causes discomfort to members of other cultures, such as Britons, Scandinavians, and Southeast Asians.

3. Value of This Type of Research

This type of research is of both theoretical and practical value. As has been shown in the papers in Tomić and Shuy (1987), 'real life' data can contribute to advances in theory development. On the basis of evidence form cross-cultural communication, the universality of the conversational assumptions postulated by Grice's (1975) 'cooperative principle,' for example, may be challenged. The maxim of quality 'Be genuine and sincere' contradicts the face/politeness rules required by the principle of harmony in Chinese and Vietnamese cultures, for example (see Young 1994). This culture clash, in fact, contributes to communication breakdown and communication conflict between people of Chinese and Vietnamese background on the one hand, and those of Western European or Anglo–American background on the other. Maxims of quantity such as 'Be brief' and 'Be orderly' are open to cultural variation in discourse rules (see *Conversational Maxims*). Central European cultures emphasize content, and formal organization necessarily becomes a secondary matter. In South Asian and some Central and Eastern European cultures, brevity is not a virtue. The whole notion of 'cooperation' may be seen, in effect, as somewhat culturally biased since in some cultures (e.g., German, Austrian, Swiss, Jewish–American, Israeli), either contrariness or putting forward one's independent viewpoint is considered desirable and more normal than collaborative discourse formation—'text sharing,' as Watts (1989) call it, a characteristic of English discourse (cf. also Wierzbicka 1991). Such variation also promotes communication breakdown and conflict. On the other hand, Neil (1996) shows that a good deal of collaboration takes places between speakers of different minority cultural backgrounds to achieve harmonious and effective communication.

Blum-Kulka et al. (1989: 63–4) do support the theoretical framework for speech act research (e.g., Searle 1969), although the degree and manner of cross-linguistic variation in rules for expressing indirect speech acts suggest to them a need to modify universalistic claims. This applies particularly to various maxims such as the maxim of tact ('Be tactful') introduced by Leech (1983). In practice, indirectness is interpreted as quite impolite and insincere in some cultures, e.g., Israeli.

The practical value of this type of research is in its application in education and training (second language teaching, cultural sensitivization in the workplace, pre-overseas placement programs, medical,

legal, social work, and teacher training in multicultural societies). The development of functional–notional approaches to second/foreign language teaching (Wilkins 1976, Van Ek 1980) facilitated the input of such research outcomes into language syllabuses. Also, business people involved in export trade and academics engaged in international networks need to be aware of the implications of this field. While communication breakdown due to grammatical or phonological interference is generally tolerated, intercultural variation in pragmatics and discourse organization is often mistaken for arrogance, deviousness, an absence of logic, or confusion.

4. Methodology

Different methods and instruments can be, and have been applied in this type of research and may be found to complement each other. These include:

(a) The collection of a large corpus of taped spontaneous interactions, representing various institutional domains and culturally heterogeneous and (for comparison) culturally homogeneous groups of interlocutors. As the influence of nonverbal factors cannot be discounted, and because of the possible impact of the interlocutor's total being, it would be useful for at least part of the corpus to be on videotape. Ethical factors and the 'observer's paradox' (the goal of linguistic research—to ascertain how people use language when they are not being systematically observed—being achieved only through systematic observation; see Labov 1972) need to be offset against advantages as sophisticated video equipment becomes smaller and more manageable and more part of the everyday experience of people.

(b) Role-played situations which can form the basis for response tests. This can be done by videoing informants while they are watching videoed role plays, but this method is very time consuming.

(c) Direct questioning and interviews are easy to administer, but it is by no means certain whether people's responses are their spontaneous responses or their statement of the norm, whatever they may declare. Also, such questionnaires present problems for some cultural or subcultural groups. Responses to attitudinal tests on discourse are intrinsically significant in cross-cultural discourse studies but they should not be regarded as satisfactory substitutes for spontaneous data.

(d) Participant observation can provide a valuable starting-point for further investigations, but it is only useful to supply data if it is recorded. Its great advantage is its naturalness and unobtrusiveness. (On the pros and cons of

interviewing and participation observation, see Heidelberger Forschungsprojekt 1975: 45–8; see also Milroy 1980.)

Until the early 1990s, most corpuses have been the result of role-play elicitations which have some of the limitations mentioned (but cf. Blum-Kulka et al. 1989). Often this type of data is the only feasible means of obtaining a corpus. For a good review of methods, see Bardovi-Harlig and Hartford (in press).

5. Cultural Value Systems

There are underlying cultural value systems which play a central role in determining intercultural variation in discourse production, processing, and expectations. Features of these include:

(a) more verbal or more literate orientation;
(b) more philosophical (content) or more spatial (formal) orientation and, linked with this, the relative importance of linearity and the relative importance of rhythmic or spatial symmetry;
(c) the relative emphasis on the individual or on the group;
(d) the relative power distance;
(e) the relative importance of harmony and conflict avoidance; and
(f) relative tendency towards concreteness and abstraction.

This influences, among other things:

(a) the extent to which people choose to perform a task in writing or verbally, the length of their turns, and the relative value of writing and speaking effectively;
(b) the organization of their written and spoken discourse, and their expectations of this organization in the discourse of others;
(c) the extent to which they will yield their turn to others;
(d) the extent to which they will explicitly contradict another interlocutor and the way they will develop an argument;
(e) who will say what to whom in what circumstances; and
(f) reader or author responsibility in written texts, i.e., is it the author who needs to take care that the text is comprehensible to the readers or is the onus on the reader to make the effort to understand it?

The analysis of discourse in cross-cultural settings is therefore a key to the understanding of cultural values of different ethnic and national groups as well as establishing communication patterns across cultures.

6. Future Research

There is a need for far more studies of discourse in cross-cultural settings involving different groups, whether culturally more similar or more distant. An increased range of data would facilitate the establishing of parameters, the separation of the relative from the absolute, and the further development of a culturally neutral mode of description. The latter would be aided if research could be jointly conducted by scholars in mirror image situations (e.g., Americans working on Japanese discourse and Japanese working on American discourse) or at least if there were more opportunities for networking in this field. Research in the twenty-first century should draw more on studies of cultural value systems, of which there is a shortage of accessible examples for many cultures.

Doctor–Patient Language
M. Lacoste

Doctor–patient language is among the most frequently studied discourse types in institutional settings. The professional dialogue between physician and patient belongs to a socially crucial and linguistically fascinating situation. After years of purely sociological or psychological approaches to the study of medical interview, the consideration of the language used in such interviews has been recently included in this type of study, thereby palpably transforming and enriching it. Most analyses deal with it from two points of view, linguistic and social, but differ in emphasis and stress one aspect more than the other.

While most of them are based on medical interviews, the analyses differ as to: (a) the models of language used by the researchers; (b) the ways the situation is viewed along the various dimensions of power, activity, and knowledge.

1. Language Models

1.1 Language as Behavior: Quantitative Studies on Verbal Exchange

Basing themselves loosely on information theory, many quantitative studies consider the verbal exchange itself to be a social indicator, and do not take the meaning into account. The variables used are, for example, addresser (speaker), addressee (hearer), duration and frequency of each participant's speech contribution, in order to compare doctor and patient with regard to use of language. Some other studies derive a version of turn-taking from conversation analysis (see *Conversation Analysis*) but simplify it in a quantitative perspective, offering some statistics on phenomena such as pauses or interruptions. What such comparative analysis has shown is that in most cases doctors speak more and interrupt more frequently than patients do, something which confirms the thesis of the asymmetrical and unequal structure of the medical interaction.

1.2 Language as a Sequence of Speech Acts

Pragmatics, and more specifically speech act theory, allows another kind of analysis based on the illocutionary force of verbal utterances. This pragmatic orientation has produced different kinds of analyses.

The simplest type identifies the basic speech acts recurring in medical communication, and then codes and quantifies the obtained data. In most cases speech acts produced by the doctor are studied in greater detail here, since patients respond more often than they initiate. This type of analysis has enabled researchers to compare medical interviews in order to see what forms doctors use most: statements, direct or indirect questions, positive or negative assessments, requests for agreements, etc. However, researchers, also being interested in sequences of speech acts, have attempted to analyze initiative/response pairs and initiative/response/acknowledgment triples. It would seem that discourse in medical interviews is characterized by this kind of triple, just as is the case for classroom discourse: both are institutionalized situations where one participant has a greater right to speak than others (Fisher and Todd 1983; see *Discourse*).

1.3 Language as a Conversational Cooperation

Ethnomethodology (see *Ethnomethodology*) has developed a theoretical perspective in which every action is considered to be coproduced by the participants in the action. Conversation analysis

has underpinned this theory with empirical studies of language in everyday and institutional settings. From the outset, doctors' and patients' contributions are seen to be strictly interrelated throughout the course of conversation. Thus, a fairly detailed examination of the occurring language sequences appears to be the only suitable way of analyzing what goes on between the doctor and his or her patient.

This approach has had a heavy impact on the analysis of medical interviews. For instance, the medical interview is no longer considered to be a homogeneous whole; rather, it is considered to be made up of heterogeneous parts, such as initial small talk, the medical exchange on the main topic, and medical exchanges on minor or side topics. Each part provides a specific context for analysis.

Various conversational procedures have been described in great detail. For instance, a fine-grained analysis including nonverbal cues shows that after the delivery of the diagnosis, a short pause is often made by the doctor, but that patients generally do not use it to take the floor and ask questions about the diagnosis. This shows that the asymmetry is not imposed by the doctor only, but is in fact cooperatively constructed (e.g., Heath 1986).

In the same way, many other phenomena such as repair and negotiation devices, disturbances in the dialogue between doctor and patient, silences, interaction openings and closings, etc., appear relevant to what is going on in the interaction.

1.4 Language as an Ideological Discursive Construction

An interest in social and cultural variation, mixed with a certain tradition of discourse analysis (especially Foucault's; see *Foucault, Michel*; *Discourse*; *Ideology*), critical sociology, and reference to Goffman's symbolic interactionism (see *Goffman, Erving*), have led some researchers to investigate the correspondence between social forms of medicine and language forms. Looking into various medical settings, such as general practice versus specific specializations, or private versus public services in the UK, etc., they have produced socio–ideological typologies of medicine. The studies do not refer to any systematic model of language; rather, they stress the importance of various language elements with regard to the context, e.g., the use of pronouns or forms of address as rhetorical devices, something which appears to be characteristic of certain types of medical discourse. By focusing on these matters, these researchers have shown the uniformity of medical discourse to be an illusion. Thereby, some interesting phenomena have been studied, such as the specific kind of discourse that occurs between doctor, parents, and sick children; it reflects the participants' different strategies, coalitions, and power relationships (Strong 1979). Interestingly

enough, investigation has shown that the use of medical jargon and technical terms by the doctor is rather uncommon, even if it does sometimes occur for strategic purposes.

Of course not all studies on medical interaction exactly fit into the frame presented here. For instance, Labov and Fanshel (1977) conducted a deep and very specific analysis on the interaction between a therapist and a patient, combining speech act analysis and a kind of discourse analysis (see *Discourse*).

2. The Characteristics of the Medical Situation

2.1 Power, Social Categorization, and Ritual

Many authors see the power of the physician as an instance of social dominance, reflected in the unequal right of interrupting, asking questions, and giving names to symptoms. This dominance appears occasionally as direct and rude, especially when patients are dealt with as if they were children. At other times, it is mitigated by social politeness and plays in more subtle ways on distance and proximity in order to preserve face for the interactants. These factors of variation need further investigation.

Social categorization is at work in medical language too. Sometimes this operates in the medical interview as such (e.g., when classifying people as good versus bad patients), sometimes it reflects larger social categories, mainly male versus female. The dominance of the doctor over the patient seems to be at its strongest whenever the patient is a woman and the doctor a man; by contrast, the least dominance by the doctor occurs when the roles are switched.

2.2 Knowledge and Expertise

The medical situation is basically one of cooperation between an expert and professional, the doctor, and a lay consultant, the patient. This has some immediate consequences in terms of knowledge dominance and discourse control by the doctor. A more careful analysis reveals the presence of subtle distinctions among respective knowledge territories: thus, there is doctor-specific knowledge versus patient-specific knowledge versus shared knowledge, etc. Following cognitive trends in the 1980s, attempts have been made to compare the medical diagnosis in real situations with the functioning of expert systems. But the medical interview in fact comprises different kinds of expertise. The doctor relies not only on 'declarative,' but also on 'procedural' knowledge; this latter is reflected in the language in the form of deictic and other context-bound devices, unlike in expert systems, where declarative knowledge is dominant (Cicourel 1987).

Following this lead, one has come to distinguish between two tasks in medical work: one is the problem-solving activity of the doctor in diagnosis

and decision; the other is the management of the interaction with the patient. Language production reflects the interplay of these two tasks.

2.3 Language and Medical Activity

Even if the main focus of interest during the medical interview has been on the dialogue, it behoves us increasingly to consider this dialogue as an element of a more global type of activity which, for the doctor, also includes instrumental actions, physical examination, consulting documents and health forms, and writing reports. Thus, a purely linguistic analysis has to be combined with an analysis of the activity.

Ethnomethodology and cognitive sociology have offered some insights into these matters. For instance, a few studies have stressed the importance of the interactional structure during the physical examination (e.g., Heath 1986).

3. Current Trends

Under the influence of these trends, the topic of doctor–patient language seems to be developing in new directions by working on data that: (a) are richer, broader, and more systematic (The intensive use of videotapes has revealed that the interrelation between verbal and nonverbal dimensions of activity is crucial. Moreover, given the increasing number of studies, data no longer come from a single source, but may be made up of sequence samples extracted from various sources. In this way, phenomena can be compared, and the way is opened towards greater generalization.); (b) include knowledge concerning phenomena that are complementary to the interaction, by means of interviews, ethnographic explorations, and information on the organization (Taking such phenomena into consideration is essential to a more relevant interpretation of discourse production.); (c) arise out of a more systematic study of the cultural, social, and organizational varieties of medical encounters (Until the early 1990s, the focus has been, with few exceptions, on Western medicine, particularly on American, British, and German health systems. Given the origins of the researchers, such a restriction may have been unavoidable, but the studies need to be broadened to encompass other cultures or subcultures.); (d) are procured from more varied medical situations, i.e., not only from interviews or medical visits in the hospital, but also from sophisticated technical examinations and other different types of medical care; (e) extend over a broader sample of participants, i.e., including not only the doctor alone, but also, as is more often the case in modern hospitals, medical teams with nurses, medical technicians, and various specialists (Löning and Rehbein 1993, Grosjean and Lacoste 1998).

Ethnography of Speaking

G. Philipsen

Speaking, the use of language in the conduct of social life, is organized in culture-specific ways. The ethnography of speaking is concerned with describing such ways of speaking and with interpreting the meanings they have for those who participate in them. It is concerned further with developing cross-culturally valid concepts and theories for interpreting and explaining the interaction of language and social life.

The term 'ethnography of speaking' was proposed by Dell Hymes (see *Hymes, Dell Hathaway*), whose writings have provided programmatic impetus to the enterprise (Hymes 1962, 1964, 1972, 1974). 'Ethnography' refers to fieldwork which culminates in a written description of the culture or way of life of a particular people, produced in such a way as to permit comparison across diverse cases. Applied to speaking, its concern is with how, in a given community, speaking is conceptualized—what symbols and meanings, premises and rules there are, pertaining to communicative conduct. Attention to native categories goes hand in hand with delineating

observed patterns of speaking, with study of a community's indigenous codes and its indigenous speech acts, events, and situations.

'Ethnography of speaking' and 'ethnography of communication' have been used interchangeably by many scholars. 'Speaking' was used initially to draw attention to the diverse, creative, and strategic ways languages are used, in contrast to language as an abstract, idealized system. Where 'speaking' is used it can be taken as a surrogate for all communicative modalities (verbal, kinesic, proxemic, etc.); 'communication' makes explicit this breadth of concern. Both speaking and communication refer to the use of codes in the production and interpretation of messages, with language being the code of primary importance in some situations but not in others. Although the emphasis is on a culture-specific approach to what speaking (or communication) is to be taken as, leaving this to be circumscribed in each case, nonetheless the ethnography of speaking emphasizes the deliberate use of signs and their interpretations, in the conduct of social life. What to call communicative resources and activities, how they are structured, what enters into them, and what their significance is to those who use them—these are left open to discovery in particular cases.

When the ethnography of speaking was proposed in 1962, established approaches to linguistic description took the phonology and grammar of a language as the principal frames of reference, an approach which privileged attention to linguistic signs within a closed linguistic system, to the exclusion of speech. Patterns of speaking had likewise been neglected in anthropological descriptions of cultures, ethnographers assuming that speech—and other modes of communicative activity—could be taken for granted rather than be made an object of investigation. The ethnography of speaking was designed to remedy the neglect of speaking in grammars and in ethnographies. Hymes proposed the ethnographic study, in diverse speech communities, of 'the situations and uses, the patterns and functions, of speaking in its own right' (1962: 16). Such studies, designed to fill the gap in knowledge which was left by established approaches in linguistics and anthropology, were to be ethnographic in basis and communicative in the range and kind of subjects which they would essay.

1. The Structure of Speaking

A fundamental assumption of the ethnography of speaking is that speaking, like language(s), can be described in terms of rule and system. Wherever people speak, they organize their speech in ways over and above those governed by rules of grammar or by physical laws. In any communicative situation, even though it might be grammatically acceptable and physically possible to make any of two or more

linguistic choices, such choices are not randomly produced. Choices as to which language to use in a particular situation (for bi- or multilingual speakers), how to address an interlocutor, whether to delete or add sounds to words, whether to speak or remain silent, are not in free variation but are patterned, according to rules which are part of the social knowledge of a particular community. It follows that much of the meaning to interlocutors, of their speech activity, is derived from knowledge of local patterns and expectations.

Speaking, from this perspective, is a complex social as well as a linguistic act. To explain speaking activities—why they occur as they do and what they mean to those who participate in them—requires reference to their social contexts. Thus to characterize what people are doing and saying when they speak, involves reference to the settings, participants, ends, act sequences, topics, and so forth, which comprise the social situation. This goes beyond the rules of language structure to a consideration of rules specifying who may say what to whom, in what language or style, to what ends, and on what occasions.

Speaking is not absolutely determined. It is patterned, but in ways which its participants can circumvent, challenge, and revise. Its rules are violated, new rules and meanings are created. Any given speech community is an organization of diversity. Its spoken life is fashioned from diverse, even discrepant, motives, practices, and preferences, but nonetheless there is, in any particular community, a knowable system in its language use. To acknowledge that the patterns are mutable and that they subsume diverse strands does not negate the fact that there are patterns, the knowledge of which speakers exploit in their speaking activities and in their interpretations of same.

The idea that speaking within a society is governed by rules which speakers can use to associate message forms with social meanings is illustrated in an extensive body of research into personal address (Philipsen and Huspek 1985). When, for example, one interlocutor addresses another with a pronoun of personal address this can involve the selection from among forms which are grammatically and semantically equivalent but whose use has social meaning. For example, although present-day English provides only one form (*you*) for pronominal address, in the seventeenth century speakers of English selected from *thee, thou, ye,* and *you*. Although these forms were equally acceptable grammatically and had the same referential meaning, which of the forms was used was highly predictable and was socially prescribed, given knowledge of the social situation: *thou* and *thee* were prescribed for address in intimate or everyday situations; *ye* and *you*, although plural forms, were prescribed as honorific forms for addressing an

individual to whom one wished, or was obligated, to pay respect or deference.

That these pronominal address forms carried social meaning was attested to not only by contemporaneous commentary but also by the usage of the seventeenth century English Quakers, who intentionally flouted the conventions of the dominant speech community. According to the Quakers' reading of the Scriptures, *thou* and *thee* were employed by Christ, and the generalization of the plural *you* to an individual addressee was, they believed, an affectation adopted vainly by popes and emperors. The Quakers prescribed that *thou* and *thee* be addressed to everyone, even to those outside their fellowship who expected *you* and *ye*, at once expressing their own conviction that 'Christ respects no man's person' and undermining what they believed to be an ungodly practice in the society at large (Bauman 1970).

Ethnographers of speaking have shown that a wide range of speaking phenomena is systematically organized in ways which are meaningful to speakers and hearers. This includes community-specific practices with regard to verbal forms, prosodic features, and extralinguistic signs. Attention to the social organization of speaking has also been extended to the structure of speech acts, activities, events, situations, and roles, as well as to the organization of greetings, leave-takings, narratives, genres, and conversations, all of which potentially can be found to have a high degree of patterning in particular contexts.

The principle that speaking is structured has been extended to the patterning of a community's entire range of speech situations and speech events. Sherzer's (1983) study of San Blas Kuna Indians in Panama, which is based on detailed observation and tape-recordings of naturally-occurring speech, articulates the Kuna way of life in terms of the patterning of resources, contexts, and uses of speaking. All major social activities among the Kuna—everyday informal conversations, teaching and learning sessions, public political meetings, and curing and puberty rituals—are defined through showing how every aspect of Kuna speaking—grammar, vocabulary, sound patterns, and gestures—is intimately linked to what is considered intelligible and appropriate conduct within these contexts.

The systematic description and analysis of all major speech situations within the San Blas community provided the basis for delineating its overall sociolinguistic structure. Most of Kuna spoken life is filled with, indeed is defined by, carefully controlled and organized talk; most major social activities involve systematically different uses of the voice and of the community's linguistic resources. But, for this highly voluble people, not every social moment is a speaking moment. Set against the prevailing preoccupation with highly ordered talk are a few contexts in which speaking is proscribed (during certain curing ceremonies in which it is believed that speaking might attract the attention of evil spirits) and in which uncontrolled yelling, arguing and fighting are permitted, even encouraged (during puberty rites and festivities). The meanings, to the Kuna, of their various ways of speaking can only be appreciated by setting each one in the context of the larger pattern. Another way that attention to the full range of speaking situations and events proved instructive in the Kuna case was the discovery that the speaking style primarily associated with particular situations penetrated into other contexts. For example, Kuna speakers incorporated miniature, momentary versions of ritual speech into everyday discourse for two different purposes: to show off (in the case of ritual specialists who could demonstrate their esoteric knowledge) and to parody the ritual context. The meanings of these momentary versions of ritual speech would be uninterpretable without the comprehensive background provided by Sherzer's description.

2. Speaking as Culturally Distinctive

Studies such as those of the Kuna, when placed side by side and comparatively analyzed, reveal that speaking, like other systems of behavior, is not only organized within a society but also organized in each society in culture-specific ways which must be discovered in each case. Societies differ as to what communicative resources are available to their members, in terms of languages, dialects, registers, routines, genre, artistic formulas, etc. They also differ in how these resources are patterned in use, in the functions served in (and serviceable by) speech and other communicative means, and in the evaluation of speaking as an instrument of social action.

Speaking is not everywhere valued equally. It is an object of a high degree of interest, elaboration, and positive evaluation in some societies. Along with the San Blas Kuna of Panama, whom one Kuna described as 'a talking people,' there are speakers on Roti, a small island in Eastern Indonesia, of whom Fox says,

> the pleasure of life is talk—not simply an idle chatter that passes time, but the more formal talking of sides in endless dispute, argument, and repartee or the rivalling of one another in eloquent and balanced phrases on ceremonial occasions... Lack of talk is an indication of distress. Rotinese repeatedly explain that if their 'hearts' are confused or dejected, they keep silent. Contrarily, to be involved with someone requires active verbal encounter.
>
> (Fox 1974: 65)

In other societies, the ideal standard for adult behavior is relative taciturnity. Among the Paliyans,

a tribal people in South India, by the time a man reaches 40 years of age he practically stops speaking altogether (Hymes 1962). In a working-class neighborhood in Chicago, local rules proscribe speaking in many contexts of male role enactment, including disciplining children, defending the honor of female relatives, and asserting oneself politically and economically (Philipsen 1975).

Differences in valuation are reflected in the distinctiveness of cultural terminologies for the act of speaking. Although all known languages have a word for 'to say' or 'to speak,' languages differ as to the number of words referring to a linguistic action. In a Mayan community of Tzeltal speakers, 416 variants of the Tzeltal form *k'op* 'speech' were elicited, all of which have the form MODIFIER + *k'op* (Stross 1974). An analogous list in English would include 'sweet talk,' 'back talk,' and a few others but would, according to the linguist who elicited the Tzeltal terms, have fewer than 10 items. Languages differ also as to which aspects of the domain of speaking are linguistically elaborated: a Chamula folk taxonomy contains many terms for ritual speech (Gossen 1974), as does that of the Kuna; St Vincentians have many words for the way of speaking called 'talking nonsense' (Abrahams and Bauman 1971).

Culturally distinctive vocabularies about the act of speaking have been of interest to ethnographers of speaking because they index or reflect attitudes and knowledge of members of the community. A portion of the social reality which attaches to the category 'speaking' (and, by extension, to social life more generally) is expressed in a people's distinctive terministic screen and vocabulary of motives for speaking. Carbaugh has written, 'As speech is identified and labeled through cultural categories, its efficacy as an action—what it is doing, what it should and should not do, what it can and can not do—is displayed' (1989: 124). It follows that as conceptions of speaking, displayed in talk, vary from people to people, so too the way of life, expressed and constituted in talk, varies across speech communities.

The transmission of information is not always or everywhere the exclusive or even primary function of speech. In the working-class neighborhood in Chicago, mentioned above, much speech behavior functions, not primarily to report or to describe, but to link interlocutors in a social relationship, and to affirm and signify the interlocutors' sameness and unity. Speech there is predominantly a means to symbolize one's place in a local social hierarchy defined in terms of ethnicity, gender, age, and place of residence. By contrast, among upper-middle-class Americans, speech about one's experiences serves not only to inform the listeners about those experiences but to give the speaker an opportunity to express his or her personal uniqueness; among these speakers a

high value is placed upon 'communication,' glossed as 'close,' 'open,' and 'supportive speech' in which the interlocutors reciprocally disclose personal information and validate the other's images of self. These examples suggest not only that something more than information transmission is being accomplished with speech, but also a difference, across groups, in what is accomplished (Katriel and Philipsen 1981).

3. The Speech Community

If speaking is examined as socially situated human action, which varies across the social fields in which it occurs, it is important to place it within the speech activity of a particular community. Investigators inspired by some version of linguistic determinism (as in the various versions of the Sapir–Whorf hypothesis) make the linguistic code the primary focus of investigation, describing a language and then ascertaining its communicative and cognitive correlates. The ethnography of speaking emphasizes a different approach, identifying a social community and ascertaining the codes, patterns, and functions which can be observed in that context. Hymes states as a working assumption: 'if there exists a set of social relationships, then there will exist communicative (and, by extension, linguistic) features considered specific to the relationship by the participants' (1968: 23).

Taking the social community as the starting point for the study of speech places the emphasis not on a single code but on the diverse variety of language codes and speech styles available to members of a community. This contrasts with defining the speech community as 'all the people who use a given language (or dialect)' (Lyons 1970: 326). It thus allows for the possibility (often realized in fact) that among a group of interacting speakers there will be two or more languages or dialects, and that one thing which is significant to know about their spoken life is how these different codes are deployed and what they mean to those who use them. It contrasts as well with a conception of the speech community as homogeneous and unitary (one language, one society), emphasizing rather that linguistic, political, social, and geographical boundaries are seldom coterminous and must be discovered in each case.

The complexities of linking social and linguistic patterns is suggested in the case of Indians in the Vaupes territory of southeastern Colombia (Jackson 1974). There are over 20 tribes, each of which has its own distinct language. All speakers in the area share rules for speaking and there is a lingua franca, Tukano, which makes communication possible among speakers who speak different primary languages. The men in the tribes are forbidden to marry within their tribe, thus assuring that their wives will have grown up learning another language in the

157

home. The wives come to live in the husband's tribal longhouse, where the husband's language is spoken and where the children learn the father's language. The longhouses, which may house several families, thus are multilingual social groups. To account for the facts of linguistic usage in this language area and within any particular longhouse in the area, requires a conception of social unit which allows for over-lapping social and linguistic boundaries.

In order to accommodate such cases, Gumperz has defined a speech community as, 'any human aggregate characterized by regular and frequent interaction by means of a shared body of verbal signs and set off from similar aggregates by significant differences in language use' (Gumperz 1968). This definition, which has been influential in the ethnography of speaking, emphasizes patterns of interaction and communication on the social side of the expression and leaves open the linguistic criteria which constitute a speech community. Hymes defines speech community as 'a community sharing rules for the conduct and interpretation of speech, and rules for the interpretation of at least one linguistic variety' (1972: 54). The emphasis is on a social community as the basis for describing ways of speaking, leaving open the criteria for identifying the social community. Hymes (1972) also includes among the social units which can provide a basis for description such related concepts as 'speech area,' in which speaking rules are shared among speakers of contiguous languages, as where speakers of Czech, Hungarian, and German may be found to share norms as to greetings, acceptable topics, and the organization of conversations; 'speech field,' as the total range of communities within which a person's knowledge of varieties and speaking rules potentially enables him to move communicatively; and the 'speech network,' the specific linkages of persons with whom one actually speaks (1972: 55).

Much of the research in the ethnography of speaking effectively conjoins the emphasis by Gumperz on patterns of interaction and the emphasis by Hymes on shared rules for conduct and interpretation of speech by focusing interest on a particular speech event (or events) and the rules which govern activity within it (them). By identifying locally defined events (or situations or scenes) for speaking, and the rules attending them, an ethnography of speaking focuses on concrete activities which are meaningful contexts for action, contexts in which patterns of interaction and rules for speaking jointly meet.

Speech events, e.g., a conversation at a party, can be viewed, in particular cases, as consisting of particular speech acts, e.g., a joke within the conversation. A speech act may be the whole of a speech event, as when a single prayer constitutes an entire rite; but more often a speech event will consist of several different speech acts. Both speech events

and speech acts, from the perspective of the ethnography of speaking, are to be discovered in particular speech communities, rather than to be assumed from a general knowledge. The discovery of such events and acts, which may or may not be named in a given language, is part of the descriptive work of the ethnographer of speaking, who seeks to account for the distinctive patterns and uses of speaking in a particular speech community.

4. A Descriptive Framework for Speaking

The initial formulation of the ethnography of speaking (Hymes 1962) included a framework for describing the particularities of ways of speaking in diverse speech communities. It was designed to provide an acontextual format for discovering, describing, and comparatively analyzing unique cases. It included four major headings: Speech Community, Speech Events, Factors in Speech Events, and Functions in Speech Events.

The speech community is the largest descriptive unit. Within a speech community, from one view constitutive of it, are speech events, locally defined contexts for speaking, each of which has an internal structure which differentiates it from other events in a community. Hymes (1962) extended Jakobson's (1960) model of a speech event by increasing the number of constitutive factors and functions from six to seven. Thus, any speech event is comprised of seven factors, including minimally, a 'sender,' who sends a 'message' to a 'receiver.' The message is sent via a physical 'channel,' implying as well some psychological connection between or among the interlocutors, and is expressed in a 'code' which is at least partially shared by the sender and receiver. The message is about something, i.e., its 'topic.' And the event occurs in a particular time and place, its 'setting.' As the factors which make up any act of verbal communication, these are factors to attend to in describing indigenous speech events and the speech acts which comprise them.

Corresponding to these factors are seven types of functions. The 'expressive' function focuses on the attitude which the 'sender' expresses toward what he is speaking about or toward the situation itself. The 'directive' function, sometimes called the 'conative' or 'persuasive' function, focuses on what the sender is asking the 'receiver' to do, in responding to the verbal message. The 'poetic' function focuses on the form of the 'message,' with particular emphasis on its artistic or aesthetic value to the interlocutors. Whether contact is established, and whether the 'channel' is opened and maintained between or among interlocutors, is the 'phatic' function, with emphasis on verbal contact being established or maintained. Whenever the interlocutors turn their attention to the 'code' itself (or the codes) being used, a 'metalinguistic' function is performed. A focus on

'topic,' the subject of the verbal communication, signals attention to the 'referential' function. The 'setting' may be the focus of emphasis in an act of verbal communication, as when attention turns to the social context or social relationship which forms a backdrop to the speech event, or which becomes the object of the speech event, as when interlocutors use speaking to define or redefine their social relationship; in these cases, a 'contextual' (or situational) function is emphasized. Although all features of a speech event may participate in all the functions, there may be specifiable linkages of factor and function, to be investigated in given cases.

In any act of verbal communication, one or more of these factors and their corresponding functions may be emphasized or foregrounded. For example, the seventeenth-century Quaker use of *thou* and *thee* rather than the conventional *you* and *ye* foreground a focus on the addressee and the directive function in the effort to induce the addressee to abandon his pretension to worldly rank rather than, say, an emphasis on the topic and the referential function. So, too, speech communities can differ in the relative emphasis placed on factors and functions. Among the Kuna, for example, there is considerable community interest in the aesthetic quality of verbal behavior, with an emphasis on message form; among the seventeenth century Quakers, 'plain speech' is preferred, with relatively less attention and valuation given to the artistic dimension of speaking.

Hymes's (1962) framework was proposed tentatively in the hope that it would provide a basis for empirical studies. In the 30 years following its publication there were some 250 studies which used its categories (Philipsen and Carbaugh 1986) and the framework was revised extensively as it was applied and tested through fieldwork. Important extensions include development of the social units of description, with attention given to speech network and speech field; a typology for characterizing societies as to the quantitative and qualitative importance of speaking; formalized procedures for rule-discovery and rule-statement; and expansion of the number of factors in speech events. The factors in speech events were reformulated in the mnemonically coded 'speaking,' thus: Setting or Scene; Participants; Ends; Act Characteristics, including both the form and content of the message; Key or Tone of the event; Instrumentalities, including Channels and Codes; Norms of Interaction and of Interpretation; and Genres.

The framework is intended to provide, not so much a checklist of things to describe, as an initial set of questions and descriptive possibilities in the study of ways of speaking in particular communities. It is intended to provide as well a format for comparison across communities, i.e., a set of categories for the articulation of similarities and differences, where these are found. In both of these regards, the framework is heuristic, set up so that the results of particular studies can be used to expand and develop it.

5. Communicative Competence

Chomsky posited an innate capacity to learn language and made the claim that 'every speaker of a language has mastered and internalized a generative grammar that expresses his knowledge of his language' (1965: 8). 'Knowledge of language' in this view consists of the ability to produce and understand a seemingly infinite number of novel, grammatical sentences in a language.

Against this notion of idealized linguistic competence Hymes has set the term 'communicative competence' (see *Communicative Competence*). Instead of referring exclusively to a speaker's knowledge of linguistic forms, 'communicative competence' refers to an ability to use language appropriately in the social situations of a speech community.

> Within the social matrix in which it acquires a system of grammar a child acquires also a system of its use, regarding persons, places, purposes, other modes of communication, etc.—all the components of communicative events, together with attitudes and beliefs regarding them. There also develop patterns of the sequential use of language in conversation, address, standard routines, and the like. In such acquisition resides the child's socio-linguistic competence (or, more broadly, communicative competence), its ability to participate in its society as not only a speaking, but also a communicating member. What children so acquire, an integrated theory of socio-linguistics must be able to describe.
>
> (Hymes 1974: 75)

Descriptions of the ways of speaking in particular speech communities reveal that as speakers humans are capable of a great deal linguistically—capable, for example, of exploiting the linguistic resources of their communities for all the varied ends of linguistic activity, including the referential, the poetic, the persuasive, etc. And as speakers they not only enact and experience but also undermine, challenge, and negotiate the local meanings which attach to and are expressed in complex arrays of linguistic activity. Thus, from the standpoint of the ethnography of speaking, speakers are seen (or heard) to display a wide range of speaking competencies, a range which the term 'communicative competence' was proposed to encompass.

6. Future Directions

Since its inception in 1962, the ethnography of speaking has developed its basic categories and modes of statement. A large body of fieldwork has been conducted under its auspices, with the aims of providing descriptions of particular ways of speaking, developing a descriptive framework, and

developing cross-cultural generalizations about the interaction of language and social life. With the development of the conceptual framework and of a body of fieldwork materials, drawn widely from many languages and many areas of the world, it is possible to begin comparative work in speaking, that is, to search for cross-cultural regularities in communicative conduct and to delineate more sharply than previously possible the dimensions of cross-cultural variation in speech behavior.

Ethnomethodology

G. Psathas

Ethnomethodology represents a new dimension in the social sciences which undertakes to study the everyday world as an achieved social reality. Its position is that all human action is irremediably indexical and reflexively related to the occasions and settings within which it occurs. Members are continually engaged in making sense, achieving intelligibility, and providing for themselves and others, interpretations of the self-same actions and utterances which, in turn, constitute the social situation in which they find themselves. Ethnomethodology proposes that the serious study of how members produce, sustain, achieve, and maintain 'the social world' requires close attention to the methods (i.e., members' methods or ethnomethods) of that production, achievement and maintenance, which methods include all manner of practical reasoning and practical actions. The discovery,

160

description and analysis of such methods constitutes ethnomethodology's main tasks.

1. Major Figures

Harold Garfinkel, the founding father of ethnomethodology, (PhD Harvard, 1952) was early concerned with the problem of social order, i.e., how members make sense of the social world. His position can be considered a radical counter position to Talcott Parsons, a major theorist in American mid-twentieth-century sociology and an advocate of positivist, structural functional analysis as set forth in his book, *The Social System* (1950) with its pattern variables and in his general theory of social action.

Garfinkel was early influenced by his readings of the German phenomenologist philosopher Edmund Husserl, the sociologist and phenomenological philosopher, Alfred Schutz, as well as by Aaron Gurwitsch, phenomenologist and psychologist, by the French phenomenological psychologist and philosopher, Merleau-Ponty, and later by the German philosopher Martin Heidegger.

Garfinkel worked most closely over a period of more than 12 years with Harvey Sacks. Their collaboration was extensive and one of mutual influence. Sacks (who died in 1975) went on to develop, with Emanuel Schegloff, what has come to be known as 'Conversation Analysis,' now considered to be one of the important offshoots of ethnomethodology. Researchers in this field include, in addition to Schegloff, Gail Jefferson in the Netherlands and many others.

Centers for ethnomethodological study in the US developed at UCLA (H. Garfinkel, E.A. Schegloff, M. Pollner, J. Heritage, S. Clayman, C. Goodwin, M. Goodwin), the University of California, Santa Barbara (D. Zimmerman, T. Wilson, G. Lerner) and at Boston University (J. Coulter, M. Lynch, G. Psathas, A. Pomerantz, R. Frankel). Ethnomethodology spread to the United Kingdom in part influenced by the visits of Garfinkel and Sacks to Manchester, Cicourel to the University of London and Manchester in the early 1970s and later by Gail Jefferson to Manchester (1979–81) and York (1982–85), and Anita Pomerantz to Oxford (1981–84). Sociologists who have been most active in the UK have included R. J. Anderson, J. M. Atkinson, G. Button, R. Dingwall, P. Drew, D. Francis, C. Heath, S. K. Hester, J. Hughes, W. W. Sharrock, and D. R. Watson. In Canada, A. Blum, P. Eglin, J. Heap, P. McHugh, J. O'Neill, D. Smith, R. Turner, and P. Weeks all have been involved in various ways in ethnomethodological studies; in Germany, J. Bergmann, C. Meier, and H. Knoblauch; in France, B. Conein, A. Coulon, R. Dulong, M. de Fornel, and L. Querė; and in The Netherlands, G. Jefferson, P. ten Have, M. Huisman, M. L. Komter, H. Maizland, and H. Houtkoop-Steenstra.

2. The Name 'Ethnomethodology'

The ethnomethodological approach studies the *methods* actually practiced (used) by *members* of society for accomplishing (doing) whatever it is they are doing (including their ways of talking about whatever it is they are doing). A serious and careful study of the methods used by members for accomplishing practical actions in the world of everyday life would result in descriptions and analyses of *the methodology of everyday life* or of the ethno- (member of a group- or the group's) methodology, or members' methods.

When Garfinkel first developed the term he was studying how the members of a jury performed (accomplished) the task of jurying. He believed (1967) that 'Ethno' seemed to refer, somehow or other, to the availability to a member of common-sense knowledge of his or her society as common-sense knowledge of the 'whatever.' But, rather than refer to members' methods for doing jury work as 'ethno-jurying' or 'ethno-law,' which would provide subdivisions of members' methods according to the (substantive) topics with which their activities were concerned, he took a broader perspective.

Perhaps, ethnosociology or 'members' ways of doing sociology' would have been an alternative term. But actually this term would not be consistent with Garfinkel's intended topic of study which is namely, how members accomplish social order, not how members describe or analyze their society. For example, in anthropology there had developed a perspective called 'ethnoscience' which aimed to discover the ways that members of a particular culture name and classify objects and products, e.g., ethno-botany, ethno-musicology, ethno-history, etc.; i.e., the particular classification systems of particular cultures at particular times and places. As Garfinkel stated (1967), his concern was with:

> the *how* it (society) gets put together; the *how* it is getting done; the *how* to do it; the social structures of everyday activities . . . studying how persons, as parties to ordinary arrangements, use the features of the arrangement to make for members the visibly organized characteristics happen.

Another way of saying this is that he is concerned with 'everyday praxis.'

The 'methodology' part of the term ethnomethodology is to be understood as referring to the 'how,' *the actual situated practices, the methods by which everyday activities are accomplished.* So, ethnomethodology represents the search to discover members' methods of accomplishing the complex tasks of everyday life, including methods of reasoning, methods of interpretation, methods of communicating, methods of interacting, methods of doing conversation, methods of doing *whatever*. And, since many of these practices are repeated and patterned, their methodical character, their orderliness,

161

i.e., their organization, can be discovered. Ethnomethodology is oriented to the discovery and analysis of such orderliness. It is not interested in explanation or the analysis of originary or causal relations.

3. Indexicality and Reflexivity

Two of the major concepts of ethnomethodology are 'indexicality' and 'reflexivity.' Indexicality refers to the fact that, for members, the meaning of what they say and do is dependent on the context in which their doing and saying occurs. Members are able to understand an action or utterance because they also know something about the time and place of occurrence, who the parties were, what had occurred previously, the relationship between the parties, what occurred next, and so forth.

Members are interested in the particularities of actions and utterances and not in standardized or idealized meanings. In achieving understanding, members take notice of and utilize all that is available to them in the context. Such details Garfinkel has called 'indexical particulars.' Indexicality is thus part and parcel of every ordinary situation of action and talk and cannot be remedied by developing standardized or idealized concepts or terms. Members do and must use indexical particulars in making sense of their circumstances; it is an essential property of the way they make interpretations, arrive at sense, decision, action, etc.

Reflexivity refers to the fact that, for members, 'the features of the real society are produced by persons' motivated compliance with these background expectancies,' that is, commonsense knowledge provides members with knowledge of the features of society and these same features are then complied with. There is thus a reflexive relation between the 'facts' about society and the ways that members use practical reasoning and commonsense knowledge to depict society. Accounts are reflexively tied to those matters and circumstances which are being accounted for. Garfinkel (1967: 4) has stated this as:

> members' accounts are reflexively and essentially tied for their rational features to the socially organized occasion of their use, for they are *features* of the socially organized occasions of their use.

Accounts reveal features of the setting, as Leiter (1980: 139) has put it,

> which, in turn, depend on the setting for their specific sense. The features of a setting that are revealed by descriptive accounts and behavior do not just explicate the setting; they, in turn, are explicated by the setting ... (B)ecause accounts consist of indexical expressions they depend on the setting for their meaning. At the same time, a feature of any setting is the production of accounts. The setting gives meaning to talk and behavior within it, while at the same time, it exists in and through that very talk and behavior.

4. The Ethnomethodological Attitude

The natural attitude, as Husserl and Schutz have shown, is the attitude of the person living in the world of everyday life. In that attitude persons accept things as they are, as they appear to be, without question. Social reality is regarded as simply there, as a world existing independent of perception. For persons who operate within the natural attitude, these 'facts' are accepted, they are not subjected to further study. That is, how members have achieved this 'sense' or 'interpretation' of what the world is, how members actually experience and describe the social world as 'factual,' how members achieve, for themselves and for others, this sense of the massive, external, 'objective' quality of the social world, is *not* studied. But it is precisely *this* which ethnomethodology wishes to study. Therefore, these methods for achieving a 'sense of the social world' as 'factual' as 'out there' as 'external' must be studied directly.

The ethnomethodologist does not say that the social world *is* this way or that, instead he or she brackets, that is, sets aside, all such ideas and beliefs and does not consider them *true or false*. Instead the focus in on *how* persons make the social world 'factual,' 'observable,' and 'real' for themselves. This would include, of course, how they talk about it. So, rather than taking a position that one version of the world or the other is 'correct' the ethnomethodologist would ask instead, how do members go about deciding matters of 'correctness' (or 'truth'), what interpretations do they engage in, how do they talk about such matters, and how do they achieve what they would recognize as and call 'correct'?

Society is not 'denied' nor does it 'disappear' as some critics have claimed. For members, society is 'always there,' but, for the ethnomethodologist, that which members consider to be 'society' is capable of study only in and through members' practices. These practices include their completed (past) activities as well as their present, still on-going activities, including speaking and acting. Past activities are available for study through recall, written materials, and in whatever ways these are referred to and retrospectively analyzed by members.

5. Ethnomethodology is not Ethnography

Ethnomethodology represents a 'methodography,' i.e., a search for the practices or methods by which the 'substantive features of the setting are made observable' (Zimmerman and Pollner 1970). It is therefore not the same as ethnography. Rather than focusing on what members do, in terms of such substantive headings as, for example in family sociology, marriage, divorce, kinship, property, (which are concerns of conventional ethnography), an ethnomethodological approach would focus on members' methods for making visible, demonstrable and accountable the particular settings'

162

features, e.g., how members recognize, describe, and make accountable, for themselves, the settings' features. The result would be discoveries with regard to a set of members' practices for accounting for such matters as, for example, 'marriage' or 'divorce' or 'kinship,' what and how categorization devices are used, how persons are 'counted' ('traced,' 'located') or not counted; how persons are 'classified' and 'unclassified,' 'collected' and 'separated' for particular purposes, and in what ways matters such as these are 'decided and done' and various types of occasions and for various purposes.

Ethnomethodological studies may discover categorization practices which underlie 'family' or 'kinship' terminological assignments and, as a collection of practices, members' categorization practices (or, as Sacks called them, membership categorization devices or MCDs) may be found to display general (or invariant) features (or structures) which hold across particular occasions, across particular speakers, etc. The discovery and analysis of 'methods of categorization' may lead more deeply into kinship terminologies or away from kinship to everyday practices in other areas, e.g., racial, class, personality, or pronoun references. The phenomenon of 'members' methods of categorization, as a members' method, is not limited by virtue of any prior preconceptions to such conventional topics as kinship (cf. Jayyusi 1984, Hester and Eglin 1997).

Ethnomethodological studies may be said to be, in part, critical of conventional work in the social sciences. The criticism is this: that conventional studies do not seek to study the phenomenon as a members' phenomenon, in all its details, following it wherever it may lead but, instead, try to specify, in advance, even before the research has begun, what the topic is exactly, how the topic is to be studied, and what form the results of the inquiry should take. For example, conventional studies demand that variables must be defined, that measurement is necessary, that statistical or quantitative analysis is essential, that empirical generalizations must be proposed, that interpretation of findings in relation to prevailing general theories (as found in the sociological literature) is necessary, and that, preferably, a casual theory be developed.

It is not difficult to understand why social scientists who accept such a model of research are skeptical and critical of ethnomethodological studies which do not appear in this form at all. Further, ethnography tries to describe the everyday practices of members of society but uses descriptions to make the events and activities observable and understandable.

Such use of description to make events observable and understandable is a way of 'constructing' everyday reality. It is a way of creating a 'sense of social structure.' That is, description would be considered by ethnomethodology to be a set of accounts whose meaning is understood from within the framework of commonsense understandings. Descriptions produce classifications, organization, coherence, relevances, rule in some matters, rule out others, etc. The use of description hides its indexical and reflexive character as a members' practice.

Ethnographers are interested in such matters as beliefs and the content of beliefs, i.e., what beliefs are about. The ethnographer may then describe what persons believe, what they tell each other to believe, what they tell their children, to whom they tell certain beliefs, how they separate their beliefs by categories such as religion, tradition, economics or politics. The emphasis in such research is on systematically collecting and observing such beliefs. In contrast, instead of being concerned with the contents of beliefs, the ethnomethodologist would consider beliefs as *members' ways of accounting to themselves for certain matters*. Beliefs, and their expression, would be studied to see how they are *used*, what *work* they actually do for members, i.e., what they *accomplish*. One discovery may be that 'beliefs' serve to explain action, for example, it may be said of a person that he watered his crops *because of his 'belief'* that water helped crops grow. The use of such words, as 'believe,' may be used, by members, to interpret, make sense of, peoples' actions (Coulter 1979b). Ethnomethodology would study the ways members have of making sense of activities and events. If such ideas as 'belief' or 'motive' are used by them then how these are used and what their use accomplishes would be subjected to study. Such studies would reveal what commonsense knowledge and understandings in their everyday meanings (uses) are for members by making commonsense knowledge and understandings the topic of study.

6. Knowing How and Knowing 'the How'

Ethnomethodology says that members of society cannot be asked how they accomplish their everyday activities and their answers then used as proportional knowledge. The reasons offered are first, that members are, essentially, *not interested* in analyzing how they do things, they are only interested in *doing* them. Second, members are not *aware*, in any explicit sense, of how they do things. Therefore, even if asked to try to explicate, or analyze, what they do, their analyses are inadequate.

For members of society, the effective test of whether they 'know how' to do something is whether they can actually do it, whether it be to have a conversation, draw a map, give directions, diagnose a disease, or give a lecture. Members operate with certain assumptions, take matters for granted, know how to do things without ever analyzing the 'how' of what they know, i.e., without ever having propositional knowledge.

163

For the ethnomethodologist, the methods which members actually use to accomplish whatever it is they are doing are an 'awesome mystery.' The discovery, description and analysis of these methods is a task for someone with a special interest, whose focus of attention will be on such matters directly. If the social scientist is to analyze commonsense understandings, simply using the same commonsense understandings that members use will not achieve the desired result. Instead, the commonsense understandings must themselves be analyzed and made into topics of study (not simply used as resources for producing the activity itself).

Ethnomethodology proposes to analyze commonsense knowledge, to discover how commonsense knowledge comes to be constituted, what produces, for members, the sense that it is 'knowledge,' and how 'knowledge' is *used*. For Garfinkel knowledge is not 'in the head' but consists of the 'doing,' i.e., knowledge is not a mentalistic phenomenon but 'praxis.' (A knowledge claim is a claim; knowing how to do something is demonstrable only in the doing itself.) However, social scientists cannot escape using commonsense knowledge (understandings) in their own work. After all, they live in the world of everyday life, they talk, write, communicate using the same language and linguistic practices as members do. Their own use of talk (language) can also be examined to discover the methods whereby talk makes 'visible' the matters talked about. Such methods as 'citation of typical cases,' 'referencing behavior to rules,' 'glossing,' 'making arguments as to reasonableness,' etc. may be methods used by members and social scientists alike.

Or, as another example, the social scientist engages in practical actions of collecting, observing, classifying, counting, describing, etc. These may be done in the same ways that 'ordinary' members accomplish these same activities, e.g., the use of categorization devices, deciding on object constancy, seeing another one like the last one, seeing an item as one of a type, etc.

Such methods, because they are used by social scientists, are not somehow transformed into 'better' or 'different' methods, or into 'scientific methods.' Rather, these methods can be subject to ethnomethodological inquiry also. The result is that ethnomethodology produces a view of all activities within the world of everyday life, even those of social scientists, as first and foremost practical activities subject to ethnomethodological analysis. This does not result in ethnomethodology becoming a 'sociology of science' or a 'sociology of sociology.' Rather the methods of sociology and all of the sciences are revealed to be practical accomplishments in their own right (cf. Coulter 1989, Lynch 1993).

Ethnomethodology is an approach or attitude or perspective by which any and all practices for accomplishing whatever, in and of the world of everyday life, are revealed as members' practices. This means that ethnomethodology is a perspective which has relevance for all the social sciences. In political science, history, anthropology, and economics, for example, ethnomethodological studies could be done of practical political, historical, or economic reasoning.

When the social sciences are studied as practical activities, the topic is not the *content* of knowledge developed by the social science but the *methods* used by the social sciences to produce and accomplish such 'knowledge,' i.e., that which is considered to be 'knowledge.' (However, this does not mean that ethnomethodology *must* analyze its own methods of practical reasoning, only that it *can* do so. And, it is not to be inferred that ethnomethodological studies will inevitably be caught in an endless infinite regress of analyzing how 'studies of the studies of the studies' are done.) Ethnomethodology treats social scientists' practices as practical activities deserving of study in themselves. In this sense, ethnomethodology can be considered a reflexive social practice which seeks to analyze the methods of all social practices (including its own). Ethnomethodology is, therefore, a genuine, reflexive social science. As such, it offers to contribute to all studies of the world of everyday life, including studies of the work of the sciences themselves.

Identity and Language

R. Mesthrie and A. Tabouret-Keller

Most linguists, following Hockett (1966) would view language as specific to the human species, notwithstanding the great respect they accord to the intricacies of the communicative abilities of dolphins, bees, and chimpanzees. Furthermore following Chomsky (1959) and Pinker (1994) they would also accept language as a biological trait or instinct. The interface between the social and the biological is, however, not much discussed in sociolinguistics. An exception is Chambers (1995) who has a chapter entitled 'Adaptive Significance of Language Variation' in his book *Sociolinguistic Theory.* For Chambers the underlying cause of sociolinguistic differences is the human instinct to establish and maintain social identity. He refers specifically to the profound need for people to show they belong somewhere, and to define themselves, sometimes

narrowly and sometimes in more general ways: 'We must mark ourselves as belonging to the territory, and one of the most convincing markers is by speaking like the people who live there' (1995: 250). Differences that exist are to a large extent explainable in terms of status and gender differences in society. Tabouret-Keller (1997) stresses the concrete physiological basis that makes speaking seem a part one's being. As oral behavior language necessarily includes corporeal elements resulting from the physiological channels that the voice has to pass through (upper ends of the digestive and respiratory tracts) which give it its phonetic qualities. Speech and language are thus frequently associated with life itself: speech–breath–spirit–soul. Most discussions of identity within sociolinguistics have however, not surprisingly, focused on group identity. We provide

165

an overview of how different schools of socio-linguistics have contributed to our understanding of the topic, before discussing the model of Le Page and Tabouret-Keller, which ties some of the strands together.

1. Regional Identity

It was well known amongst dialectologists of the nineteenth century that speech carries geographical overtones. Many language varieties and languages have names that tie them to a locality and confer a badge, if not an identity, upon their habitual users. Even where a specific name does not exist and the localized speech form is taken for granted amongst people who live in close networks with little geographical mobility, an occasional visit out of the terrain is enough to jolt a speaker into linking geography with a sense of personal and/or group identity. One of the pioneering studies of modern sociolinguistics, Labov's Martha's Vineyard study (see *Dialect and Dialectology*; *Sociolinguistic Variation*; Labov 1963) is ultimately concerned with the effect a localized island accent has on a sense of identity. Crucial to identity formation was the relationship between local people who relied on the tourist economy to boost income, and the rich tourists who tended to overrun parts of the island in the summer. Labov showed that a particular feature of accent (centralized first elements of diphthongs /aɪ/ and /aʊ/) was sufficient to distinguish the speech of younger Vineyarders from older inhabitants of the island whose own speech norms in this regard had over time been falling in line with those of the surrounding mainland areas. Young people showed a reverse pattern which accentuated the centralized diphthongs. Labov remarked that using a pronunciation like [rəɪt] ('right') is a subconscious affirmation of belonging to the island and being one of its rightful owners. It was, as a later commentator on this study, McMahon (1994: 242) remarked, like wearing a T-shirt that says 'I'm not a tourist, I live here.' This is not only a regional statement however, but a social one too, as the islanders in general belong to a lower socioeconomic category than the rich summer tourists from the mainland, from whom they seek to differentiate themselves linguistically.

2. Social Identity

Indirectly following the lead of intellectuals like Saussure (1857–1913) and Durkheim (1858–1917) most sociolinguists argue that the social group is more important than the individual as far as language use is concerned. An important strand in this line of thinking is Labov's model of social variation (see *Sociolinguistic Variation*; *Sociophonetics*; *Labov, William*). Labov (1966) showed that some variables like postvocalic (r) in New York City

(the /r/ after vowels in words like *car* and *park*) show fine or gradient stratification according to social class. The variable is subject to 'shared norms and common evaluation' by the society at large, with higher status groups making proportionally higher use of [r]. Labov showed that with respect to other variables like (th) the same society might display a class division; stratification is sharp rather than fine, with a chasm between the working class and lower working class. This kind of stratification seems even more applicable in parts of the UK (Trudgill 1978) and pre-industrial contexts elsewhere (see Rickford 1986, for Guyana).

Similarly the model of social networks which places central emphasis on the types of links between individuals within a network (see Milroy 1987; *Social Networks*) has a great deal to suggest about identities that are formed by habitual interaction, especially linguistic interaction. Also evident in the social network model is the interaction between region of origin and social class.

3. Ethnic Identity

In some societies, ethnicity may be more salient than class stratification and language may play a key role in reflecting and indeed in maintaining and 'reproducing' an ethnic identity. Ethnicity is notoriously difficult to define and may not be as objective a phenomenon as sometimes assumed. Edwards (1985: 8) quotes Weber (1966) who regards ethnic groups as 'those human groups that entertain a subjective belief in their common descent—it does not matter whether or not an objective blood relationship exists. Ethnic membership differs from the kinship group precisely by being a *presumed* identity.'

Edwards therefore argues against the notion of a 'primordial ethnicity' which one sometimes finds in the literature on language maintenance. Edwards (1985: 163) stresses that group identity can survive language shift. On the other hand it is difficult to imagine a sense of ethnicity that does not entail significant differences in language use (e.g., religious and cultural vocabulary, and nuances of accent are well-attested in ethnic dialects). Postmodern people of the twenty-first century have multiple identities, playing out a number of roles in a single day, each of which may require different language choices.

In some contexts a first language may not be the only, and possibly even the main, bearer of a sense of community identity. In connection with the situation in Cameroon, Wolf (1997) argues that speaking English as a second language gives a sense of unity to 'Anglophone' Cameroonians, rather than their mother tongues, which are ethnically marked. In this context Wolf sees language as a prime shaper of ethnicity, but de-emphasizes the role of the mother tongue. Ethnically diverse groups have redefined their primary ethnic allegiance via a specific type of

bilingualism (see *Bilingualism, Societal*). In some situations (though not in the Cameroonian situation described by Wolf) such a redefinition may eventually open up the way for language shift, with possible further implications for readjustments of identity.

4. Gendered Identity

In earlier gender and language research (see Lakoff 1975, *Gender and Language*) the main aim was to demonstrate a broad linguistic split between the sexes. Subsequent research has increasingly become more nuanced. Eckert (1989) stresses the interplay between gender and social class in setting up various overlapping identities. From anthropology and Gay Studies has come the notion that a simple two-way dichotomy is misleading; that there are differing degrees of masculinity and femininity (see *Gay Language*; Johnson and Meinhof 1997, Kulick 2000).

5. National Identity

Many writers see nationalism as a kind of ethnicity writ large (see *Nationalism and Language*), but with geographical borders and formally defined structures. Edwards (1985) writes that nationalism, with or without a linguistic component, is based essentially upon the same sense of groupness, which informs identity. For Anderson (1985) the state is able to exploit the possibilities offered by the print media to form 'imagined communities' within artificial physical boundaries. How the rise of the Internet (see *The Internet and Language*) and its 'virtual' communities affects Anderson's thesis remains to be seen.

Modern nation-states can weigh heavily upon the idealized union of language and identity by commanding many ways by which a language is forced upon their citizens, be it by constitutional definition of an national, official or State language, or by one of many other ways like the control over the language(s) allowed for school education, for law and justice, etc. As a matter of inherent paradox, though not openly expressed, the formation of states rests on discourse (and eventually on law!) justified by mother-tongue ideology, and calls on population territorial identity at the same time that these States in setting their frontiers ignored the language people used and their identity. As a result, frontiers between states seldom coincide with dialect areas.

Multilingual situations illustrate the two aspects of identification by language features or by a language label. Linguistic features deriving from language contact may identify a bilingual speaker. According to the social situation, this gives rise to feelings of devalorization, discrimination, eventually of exclusion from the dominant group, or feelings of familiarity, recognition, complicity among those who have this particular language in common or share the contact situation. Mastery of the dominant language is regarded as witnessing allegiance to the State which imposes it, and integration to a community mistakenly based on a unique linguistic identity. Such sociolinguistic constraints point towards the subjective difficulties which may arise in contact situations.

6. The Projection Model of Le Page and Tabouret-Keller

The work of Le Page (1978) and Le Page and Tabouret-Keller (1985) forms a useful way of tying together the different strands of research on identity. In this model individuals have priority; well defined social groups may or may not exist beforehand. For Le Page and Tabouret-Keller (1985:14) linguistic behavior is 'a series of *acts of identity* in which people reveal both their personal identity and their search for social roles.' In this view identity and language use are potentially fluid. In the highly multilingual and heterogeneous communities they studied in the Caribbean the researchers found it necessary to pay attention to the processes of emergence and disintegration of identities in relation to linguistic processes of focusing and diffusion. The terms 'focusing' and 'diffusion' are based on the metaphor of the cinema with the projection of images. Speech acts are acts of projection: the speaker projects his inner universe via a common language (with its nuances of grammar, vocabulary, and accent) or via a particular choice of language where choices exist (in multilingual settings). The speaker implicitly invites others to share his projection of the world, insofar as they recognize his language as an accurate symbolization of the world, and to share his attitudes towards it (1985: 181). The feedback he receives from those with whom he talks may reinforce him, or may cause him to modify his projections, both in their form and content. To the extent that he is reinforced, his behavior in that context may become more regular, more focused; to the extent that he modifies his behavior to accommodate others it may for a time become more variable, more diffuse. In time, however, the behavior of the group—that is, he and those with whom he is trying to identify—will become focused. The individual thus creates for himself patterns of linguistic behavior so as to resemble those of the group or groups which he wishes to be identified at different times. Le Page stressed four provisos to this hypothesis:

(a) that one can identify the groups;
(b) that one has adequate access to the groups and the ability to analyze their behavioral patterns;
(c) that the motivation for joining the group must be sufficiently powerful and is either reinforced or lessened by feedback from the group;
(d) that one has the ability to modify one's behavior.

167

Le Page and Tabouret-Keller's model thus teases out the kind of variation evident in a society from its historical moments: is it a society in the making or in flux (diffuse) or is it historically speaking, focused?

7. Critical Sociolinguistics and Identity

Critical sociolinguists and post-structuralists in general (see *Critical Sociolinguistics*) have a different 'take' on issues of identity. Their starting point is not the predefined group; but power relations in societies and the ideologies they engender. Their approach to the subject of identity is therefore not an essentialist one—the individual subject is 'decentered.' Power is considered to be diffused, concealed, or buried by the effects of ideology, and therefore requiring an archaeology of its own. For Foucault (1972) (see *Foucault, Michel*), the most important thinker on the subject, power is everywhere, it is not a commodity that can be acquired but exists in all kinds of relations including the political, economic, and educational arenas. In his early work Foucault pursued 'the constitution of the subject,' a theme Althusser had brought up in connection with the effects of ideology. The individual subject (i.e., human being) was for Foucault not imbued with an individualized consciousness or personality, rather s/he was an 'empty entity,' the intersection point of a number of 'discourses' (see *Discourse*).

Foucault's notion of speaking subjects being 'empty entities' stands in stark contrast to more humanist approaches, which see people as individuals having a full 'command' over language. The implication of Foucault's approach is that to understand the self (or speaking subject) researchers have to study language and discourse. For some critical theorists there is a sense in which language speaks through people! Potter and Wetherell (1987: 109) comment on this position from a perspective within social psychology that has come to be called social constructivism (or the social construction of identity):

> In this tradition people become fixed in position through the range of linguistic practices available to them to make sense. The use of a particular discourse which contains a particular organisation of the self not only allows one to warrant and justify one's actions ... [as an individual being], it also maintains power relations and patterns of domination and subordination. In constructing the self in one way, other constructions are excluded, hence to use a common phrase found in this tradition, the creation of one kind of self or subjectivity in discourse also creates a particular kind of subjection.

Few sociolinguists would go all the way in accepting Foucault's idea of completely decentered human subjects, which amounts to a Whorfian (see *Sapir–Whorf Hypothesis*) view of how language controls consciousness. It is difficult to comprehend, despite Foucault, how discourses originate without some kind of human agency. It is nevertheless easier to accept that once discourses arise, they may 'flourish' via the individual child or adult subject. Research on identity in this tradition is rather abstract and lacks the empirical richness of some of the more conventional studies cited above. But the effort to link ethnicity with forces beyond the level of the group, that is to power relations that predate the birth of any particular individual, is a perspective that is worthy of consideration.

8. Conclusion

The study of identity is something of a by-product of sociolinguists' interest in other topics, e.g., language variation. There are tensions between approaches that take individuals and groups for granted, those that take power relations rather than individuals as central, and those that stress individuals over groups. All research on language and identity starts from the assumption that identities make sense, that they are meaningful. Although some answers have been given in terms of symbolic functions of language and identities as language-embedded elements, the question remains open for the social psychologist and the sociolinguist how exactly these symbolic functions operate. As yet, we do not know enough about the ways in which identities themselves mediate between the various symbolic resources of different groups and also how, under certain conditions, they function as a means of power in normative social systems.

Kinesics

A. Kendon

The term *kinesics* was introduced by Ray L. Birdwhistell in 1952, to refer to the study of the communicative role of body motion in interpersonal interaction. Elaborating on certain ideas in anthropological linguistics then gaining currency, he suggested that bodily carriage, posture, gesture, facial expression, and the like, should be looked upon as communicative modalities that, like language, are culturally patterned. This contrasted with the view, widely held at the time, that such phenomena are merely symptoms of feelings or expressions of character. Birdwhistell also proposed that if body motion functioned as a communicative code analogous to language, it could be analyzed using methods similar to those used in linguistics—specifically, the analytical methods of American structuralism (Hymes and Fought 1981). Although this aspect of Birdwhistell's suggestions has not been followed out in detail, the communicative approach to body motion he articulated has proved very influential.

1. Early Studies

That bodily posture, movement, and facial expression play an important role in human communication has been recognized since antiquity (Schmitt 1984). Thus, Cicero in his *De Oratore* and Quintilian in his *Institutiones Oratoriae* wrote about bodily conduct in public speaking. Quintilian's discussion was an important source for treatises devoted to this topic that appeared from the seventeenth century onwards, for example by Bonifacio (Italy 1616), Cresollius (Paris 1620), and Bulwer (London 1644). Of the later works, one of the most influential is Gilbert Austin's *Chironomia* of 1802, used by writers

of textbooks on the art of public speaking for at least a century. In the eighteenth and nineteenth centuries, treatises on the use of the body in acting also appeared, of which the most important include the works of Engel (Germany, 1785–86) and works expounding the system of Delsarte (France, 1811–71).

In the nineteenth century, scientific works in this field began to be published. Facial expressions were studied by anatomists such as Sir Charles Bell and physiologists such as Duchenne, and Darwin discussed them in terms of evolutionary theory in his *On the Expression of the Emotions in Man and Animals* of 1871. A long tradition of investigation followed, especially in psychology, with particular emphasis on the question of the universality of facial expression (Ekman 1973, 1982). Gesture, regarded as being relevant for theories of language origins, was discussed by Edward Tylor in anthropology (1865) and Wilhelm Wundt in psychology (1902). Garrick Mallery dealt with studies of American Indian sign language in a comparative perspective in a publication that appeared in 1880. Both Mallery and Wundt drew upon the earlier work of Andrea De Jorio, whose *La mimica degli antichi investigata nel gestire napoletano* of 1832 is possibly the first truly scientific book in this field (cf. Schmitt 1984, Kendon 1995). In this treatise, gesture and other bodily expressions observed among the Neapolitans are described and, by drawing comparisons with pictorial and sculptural works of antiquity, the author seeks to demonstrate historical continuity between the expressions of ancient and modern inhabitants of Naples. He also discusses links between gesture and spoken language, the importance of context for interpretation, the

relationship between gesture, form, and meaning, and other issues still of importance today.

2. Development of the Kinesic Approach

For the first half of the twentieth century, the study of facial expression, posture, and gesture was dominated by the viewpoint of an individualistic psychology, although there were those such as the linguist Edward Sapir (see *Sapir, Edward*) (1927) who pointed out that it could also be looked upon as a culturally patterned communicative code. This view was also held by Sapir's teacher, the anthropologist Franz Boas (see *Boas, Franz*), who provided the theoretical basis of Efron's (1972) study of cultural differences in gesticulation, first published in 1941. However, the view that body motion could be considered as a form of communication did not become widespread until the 1950s (Ruesch and Kees 1956). Two factors were important here. First, mental disorder began to be seen as a disorder of communication rather than as a consequence of heredity or infantile trauma, so that communication in psychotherapy became a focus of research. Second, following the expansion of US activities overseas after World War II, there was an increase in awareness in the USA of cultural differences in interpersonal conduct. Birdwhistell, in laying the foundations of kinesics, worked in association with the linguist G. L. Trager and the anthropologist E. T. Hall at the Foreign Services Institute in Washington, DC, a division of the US State Department charged with foreign language training for diplomats. Both Trager and Hall insisted on the importance of including training in the interactional conventions of the cultures associated with the languages being studied and they together formulated a framework for the study of communicative functions of spacing, time, and body motion as culturally determined and structured in ways that were thought to be analogous to the structure of spoken language (Hall 1959).

Together with the anthropologist Gregory Bateson and the linguists Charles Hockett and Norman McQuown, Birdwhistell also took part in a project known as the 'Natural History of an Interview,' the first attempt to provide a comprehensive and integrated analysis of the linguistic, spoken and kinesic components of interaction. Though never published, this study, begun in 1956, played a central role in advancing the conceptual development of kinesics and is the source of Birdwhistell's most systematic statement of the subject (Leeds-Hurwitz 1987). In addition, the sociologist Erving Goffman (see *Goffman, Erving*), with his early work on 'self-presentation' (Goffman 1959) and his studies of the ways in which people, when in each other's presence, regulate every detail of their conduct in accordance with shared norms (Goffman 1963), provided further concepts important for later developments in kinesics.

3. A Contemporary View

Body movement functions communicatively in interaction in a number of different ways. It serves as a source of information about an individual's background, status, and situational role; it functions in creating and sustaining the context essential for the process of specific encounters, such as conversations; it has an intimate relationship with spoken expression, contributing to the interactional organization of utterances, to the way in which they are structured, and to the expression of content.

3.1 The Communication of Background, Status, and Role

People in one another's presence unavoidably provide each other with information about themselves in terms of which each guides his conduct in respect to others. Body size, carriage, clothing, and hair-style, patterns in the use of facial expressions and manner, and amplitude of gesturing and other bodily movements are, to a greater or lesser degree, culturally patterned, and contribute information about the sex category and age-grade of an individual, as well as providing clues to social class, geographical origin, social status, and situational role (see La Barre 1964, Birdwhistell 1970; see also Ekman and Friesen, and Seaford in Kendon 1981). Further, as Goffman (1959, 1963) has made clear, since, to some extent, these aspects are under the voluntary control of individuals, they can be managed by them to ensure that the kind of information that is conveyed is consistent with their own view of themselves and to ensure that they are perceived by others as fitting a certain part or role within a given situation, whatever this may be.

3.2 The Regulation of Interaction

The activities people are engaged in are also sources of information. For example, pedestrians on a city street, in virtue of how they walk and where, when and at whom they look, provide each other with information about the direction in which they are moving, whether or not they take account of others nearby, whether they are intent on reaching a certain goal or just surveying the environment. All of this is made use of in the process by which collision-free passage is achieved.

Co-present individuals often engage in interaction in which there is a sharing of attention, as in conversation. Participants in such 'focused interaction' (Goffman 1963) tend to arrange themselves spatially in a fashion that distinguishes them as a group, distinct from others who may be about. It is common, for example, for two or a few individuals talking together to arrange themselves so that they

can look at each other easily and this often gives rise to an arrangement that is roughly circular. Such arrangements, cooperatively maintained, provide a way in which people can display to one another the part they are currently playing in the event. The shape of the arrangement also provides clues to its organization. For example, if it is the role of one person to talk more than the others, or if it is the role of one person to control the activities of several others, then the person who talks more, or is in control, tends to assume a distinct spatial position, so that the spatial arrangement of the group as a whole is different from the arrangement seen where the roles of all participants are similar.

Especially in seated groups, the sustained bodily postures of the participants show a patterning that is consistent with their manner of participation. Scheflen (1973) showed that conversationalists typically display a restricted range of postures, and that changes in posture and bodily orientation are often coordinated with changes in the kind of interaction that is taking place. For example, in interviews, where the interviewer may alternate between asking questions and listening to the interviewee's replies, consistent changes in posture may be observed which are associated with these shifts in activity. Sustained postures, Scheflen showed, serve as visible brackets for a given phase of activity and shifts in posture can mark changes from one phase of activity to the next. Sustainment of posture and changes in posture, thus, may play an important role in the process by which the shared orientation framing the interaction is achieved.

The question of how participants organize turn-taking in conversation (see *Conversation Analysis*) has been much studied. Included here are issues such as, how participants know when to speak or when to listen, how it is recognized to whom an utterance is directed, how participants show attention or inattention, how they provide responses to what another is saying, how they show they are or are not ready to take a turn at talking, how the difference between finishing a turn at talking and suspending it while searching for what to say next is displayed, and so on. Gaze direction, head and face gestures, posture shifts, and other bodily movements have all been shown to play an important role (Goodwin 1981, Heath 1986). Some studies have shown that there are dialect-like differences in how these aspects of interaction are handled, which, in encounters between people of different cultural backgrounds, can be a source of difficulty (Erickson and Shultz 1982).

3.3 Kinesics, Speech, and Language

Body motion, then, plays an important role in making possible the attentional coordination neces-sary for focused interaction and in providing cues that are important for the regulation of various aspects of spoken utterance exchange. It also plays a role in conveying information about the phrasal structure of what is being said, as well as about content. Birdwhistell summarized observations on how head, face, and hand movements associated with spoken utterance pattern with stress and intonation and he showed that, in addition to providing visual markers of linguistic stress, differences in the directions of these movements are consistently associated with the different referents of the pronouns and demonstratives they accompany; thus, they also convey semantic information as well. Studies of the hand movements often associated with speech have shown that these are organized in parallel with the phrasal organization of speech, and that the hand-shapes and movement patterns employed may depict shapes and movements that represent actual concrete objects or actions, which either are being referred to directly by the speaker or which serve as metaphors for more abstract concepts. Evidently, visual imagery is drawn upon directly as a source of expression alongside syntactically organized lexical expression (McNeill 1992).

Communicative bodily actions can also become stabilized and established within a community as so-called 'emblematic gestures.' As such they can function like spoken items, either as if they are interjections or as true words. Further, if circumstances prevail in which speech cannot be used, whether because of deafness or for ritual reasons, such lexical usages of bodily movement can become very elaborate, and 'sign languages' may emerge (see *Sociolinguistics of Sign Language*).

Kinship Terminology

E. L. Schusky

Linguists and anthropologists have been studying kinship terminology for more than a century. Linguists have tended to analyze this terminology in terms of how it relates to the rest of language while anthropologists have regarded kinship as a part of society and analyze it for its cultural components. The former view treats kinship terminology strictly as one part or one domain of language; the latter approach assumes kinship terms are a cultural construct that relates people in unique ways.

Both approaches must recognize that kinship terminology exists in all languages, and that all peoples have approximately the same meaning for 'relative.' That is, a domain of kinship is precisely marked off by the idea of 'relative.' Also, almost universally people have terms of address for some relatives that differ from terms of reference; they use a term like 'dad' when speaking to him and a term like 'father' when speaking about him.

Everywhere people have modeled their relations on biological connections, and their terminology shows they make distinctions between relatives of descent and relatives of marriage. Descent ties produce relatives known as 'consanguine'; relatives through marriage are 'affines.' Although exceptions occur, kinship terminology distinguishes consanguine from affine. Students of kinship study what other distinctions among relatives are made on the basis of kinship terminology. When they found that the reasons for distinctions varied widely among peoples and the resulting kin networks were organized quite differently, they searched for factors in the variation. The discovery of variables causing differences in kin organization remains basic in the study of kinship terminology in the 1990s.

If kinship is regarded as only a part of language, then the variables examined are linguistic. Kinship terms are made to fit the rules of the rest of language. When kinship is regarded as part of society and culture, the variables examined are sociocultural ones, or culture is regarded as adaptive and kinship is assumed to be a product of adaptation of the environment.

1. Origins of the Study of Kinship Terminology

In the nineteenth century, Lewis Henry Morgan studied the Seneca of the Iroquois nation and discovered they organized their kin very differently from Europeans. Their mother's sisters' children and father's brothers' children were classified as 'broth-ers' and 'sisters.' Thus, Seneca had many more siblings than any Indo-European speaker. When Morgan discovered that other Indian tribes classified relatives in the same way, even when speaking a completely different language, he proceeded to send questionnaires all over the world to collect kinship terms. The schedules of terminology showed that some peoples in all continents classified their kin the way Seneca do.

Morgan also discovered various other systems of kinship terminology. Many peoples in the Pacific, for example, regarded all their cousins as brothers and sisters, lacking any kinship term for 'cousin.' For these people, all the siblings of mother and father were classified as 'mother' and 'father.' In parts of Africa, Morgan found that each of the cousins had their own kinship term with a separate term for each of the siblings of the parents.

Like other social evolutionists, Morgan assumed that such cultural differences must represent stages of evolution, and that his own kinship system must represent the highest level of development. Thus, whatever was most different from Indo-European organization would represent 'primitive man.' That system must be the Pacific one which failed to recognize any differences between siblings and cousins or parents and uncles and aunts.

To generalize these differences, Morgan spoke of 'descriptive' systems of kinship terminology versus 'classificatory' systems. A descriptive system had kinship terms for lineal relatives, such as 'father,' 'grandfather,' and 'great-grandfather' that were distinct from 'uncle' and 'great-uncle.' A classificatory system grouped some collateral relatives, such as 'cousin' or 'aunt' with 'sister' or 'mother.' Hawaiian kinship terminology that grouped all collaterals with lineal relatives was an extreme example of a classificatory system; English terminology that separated every lineal from every collateral exemplified a lineal system.

In his major work on kinship terminology, Morgan explained these different systems as arising from marriage practices. He reasoned that 'primitives' first had group marriages so that offspring did not know their true mothers and fathers, that everyone in the family a generation above them must have been seen as mother and father. All the children of the same generation would be brothers and sisters to each other. In contrast, where marriage had evolved to a monogamous state, lineal relatives could be kept separated from collaterals and a descriptive system of kinship terminology would arise. In later work, Morgan saw that kinship systems also correlated with types of property and its ownership. These types were also forced into stages, with Morgan insisting on a 'comparative study' that placed the different systems on an evolutionary continuum.

Edward Tylor, a contemporary of Morgan, took kinship studies in a different direction. He noted that various peoples around the world instituted a practice of mother-in-law avoidance, sometimes suggesting the avoidance through the term for mother-in-law. His focus was upon correlating the practice with other social factors, and he discovered that avoidance commonly occurred where people practiced matrilocal residence, a custom of residing with the bride's original family. This line of research ceased until development of statistical techniques for proving correlations, but it focused attention on the necessity to see kinship behavior within the arena of culture.

2. Kinship Terminology as a Part of Language

Twentieth-century scientists rejected social evolution asserting all cultures were of equal value. Evolution suggested a superiority of European and American peoples, which anthropologists denied. In his rejection of social evolution, A. L. Kroeber misinterpreted Morgan's definition of the term classificatory in order to force kinship terminology totally within the realm of language and make English appear to be highly classificatory.

From this view, Kroeber proceeded to examine how languages of other peoples classify or categorize their relatives. He saw his search as demonstrating the equal validity of all cultures; it was meant to delineate the principles by which peoples of the world formulate systems of kinship terminology. These principles were used in similar ways by everyone.

Kroeber listed eight principles. Most systems distinguish people in the same and different generations; they indicate differences between lineal and collateral relations; they mark differences of age within the same generation (lacking in English); they indicate sex of the relative; they denote the sex of the person through whom a relation exists (lacking in English); they discriminate consanguine from affinal; they denote whether the relative is dead or alive (lacking in English). In sum, the word 'niece' denotes a relative a generation below the speaker, a female, and a collateral.

Viewing kinship terminology as language, Kroeber argued that when the same word is used for male cousin and husband (as it is in some Indian languages), the correspondence is due to both relatives being of the same sex, the same generation, of opposite sex to the speaker, and both collateral. Morgan would have had to argue that the correspondence was due to a marriage practice that directed one to marry a cousin (a practice that was found to be more widespread than Kroeber realized). Kroeber concluded that the identical terms had to be explained as a linguistic phenomenon resting on the same psychological mechanisms that ordered other mental classifications. The ultimate reasons had to be determined by psychology.

While Kroeber searched for general, psychological principles to explain kinship terminologies, W. H. R. Rivers was developing a genealogical method for studying kinship that advanced anthropological fieldwork. Like Morgan, Rivers saw kinship as cultural and recognized it as closely tied to most other cultural aspects. Unlike Morgan, he did not attempt to tie practices to evolutionary stages; rather

he sought to show how kinship terminology designated the roles that kin were to play toward each other, fitting their kin groups into the total society. In sum, Rivers' work continued to emphasize how kinship terminology reflected social relations while Kroeber was battling for a psychological and linguistic explanation.

3. Functional Theory and Kinship Terminology

The next generation of anthropologists further developed Rivers's thinking, although they gave Emile Durkheim credit for their inspiration. A. R. Radcliffe Brown led in the study of kinship terminology, believing it basic for the understanding of society or social structure. Following Durkheim's view that society was an organic whole, Radcliffe-Brown posited the parts of social structure to be related to each other as the digestive, respiratory, and nervous systems are related to each other, not causally but functionally. Thus politics, religion, and economics were mutually tied together; for Radcliffe-Brown, kinship would likely have been the skeleton of social structure, providing a framework for the other systems of the organic whole.

To study kinship terminology, Radcliffe-Brown relied on the development of scientific principles that explained why two or more relatives were called by the same term. For example, 'father' and 'father's brother' are often grouped together as are 'mother' and 'mother's sister.' He argued that such classification arose from a principle of 'the equivalence of siblings.' Two men who were brothers were easily merged into one role; likewise with two sisters. The principle was further followed when a person called his mother's sisters' children, 'brother and sister.' They were, after all, children of his 'mother.' The principle sometimes even explained why siblings of opposite sex were virtually merged; in some places father's sister becomes a 'female father.' That is, the kinship term has 'father' as a stem, with a feminine affix. The mother's brother then becomes a 'male mother.'

Another principle of Radcliffe-Brown's was a 'lineage principle.' Members of a descent group could be considered as close to each other as siblings, especially when viewed from the outside. So a member of a matrilineage could merge together all the male members of his father's matrilineage, in effect calling them all 'father' even when some of these 'fathers' were in the same or descending generations. Systems of terminology that classify 'fathers' in such a way are called 'Crow.' In an 'Omaha' system of terminology, women in different generations but in one's mother's patrilineage would all be grouped together.

The two different systems appear to be mirror images of each other in their terminology with Crow descent passing through females while descent is through males in Omaha. Crow–Omaha terminologies remain central in discussions of kinship, and Meyer Fortes has detailed their similarities. Radcliffe-Brown's development of 'principles' to explain such organization of terminology differed little from Kroeber's principles, although Radcliffe-Brown would have insisted his theorems rested on social facts, not psychological ones.

Fred Eggan extended Radcliffe-Brown's work to include ecological variables. In a controlled study of social organization among the western Pueblo Indians, Eggan showed how adaptation to irrigation in the Rio Grande Valley influenced kinship. He also emphasized the importance of Spanish contact and its influence upon social organization, demonstrating the importance of history for understanding kinship.

George Peter Murdock worked along parallel lines but with a different methodology. While Radcliffe-Brown and Eggan examined in depth a small number of societies to develop their principles, Murdock developed a large inventory of different cultures and began to test hypotheses statistically. In effect, he perfected the work that Tylor had begun.

Murdock's major discovery was determining the reasons for the different systems of descent. He concluded that the ecological adaptations leading to rules of residence were basic in evolving kinship terms. Horticulture often meant that females controlled plots of land so daughters remained home at marriage, in matrilocal residence. As daughters, then daughters' daughters, followed by daughters' daughters' daughters stayed in place to form a matrilineage, kinship marked off the importance of matrilineal relatives. Eventually the terminology would be Crow, but it could begin like that of the Seneca.

As Murdock's work progressed he came to realize that kinship terminology resisted change more than other parts of society. A people might leave horticulture, such as practiced by the Mandan and Hidatsa Indians, to become bison hunters once the horse was introduced. The Crow Indians did just this, separating from the Hidatsa. When discovered by anthropologists, the Crow were living much like bilateral peoples, no longer practicing matrilocal residence, but they maintained a Crow system of terminology. Recognition that kinship terminology can be used as an index of culture change meant that it became a subject of interest to ethnohistorians and even archaeologists.

While Murdock built a case that kinship systems arose because of ecological adaptation, Claude Lévi-Strauss revolutionized thinking about kinship by claiming that most of what was structured in culture was because of the way the mind works. Art, mythology, and face painting are structured because the brain processes information by oppositions. The structure of kinship was due to the working of the mind.

Lévi-Strauss argued that kinship began with the origin of marriage. It was a form of alliance that tied relatives by descent to other descent groups. A basic structure or opposition was built into kinship by the contrasting groups of those one could marry and those one could not marry. 'Sister' was an obverse of 'wife' just as 'brother' was an obverse of 'husband.' Within the descent group, relationships were like those between siblings; relationships outside the descent group were ones of affinity. These relatives were 'in-laws.' Kinship terminology often reflects these oppositions, a fact noted by Morgan and expanded upon by Kroeber.

4. The Semantic Analysis of Kinship Terms

In a compromise between the grand theory of Lévi-Strauss and the pragmatism of Kroeber, Floyd Lounsbury proposed a new method for the analysis of kinship terminology which he borrowed from linguistics and logic. He proposed to limit examination of kin terms to a formal analysis. His first step was to identify all the basic kin terms of a language; he then generated all the rules that predicted when a term would be used for a particular relative. The research was to be judged solely on its parsimony and its sufficiency. The set of rules ought to account for all of the relatives called by a single term, and all of the kinship terms ought to be predictable by the rules. The method emphasized necessary and sufficient causes.

Lounsbury realized that most anthropologists would be dissatisfied with parsimonious explanation because it overlooked the many ways in which kinship is functionally related to the rest of culture, but he reasoned that such a concise account was the best means for making cross-cultural comparisons. He hoped that formal accounts would best pinpoint the common features giving rise to the various types of kinship systems.

In his own account of Seneca kinship, Lounsbury pointed up a number of components that distinguish one relative from another in the domain of kinship. These components are much like those of Kroeber; what Lounsbury added was a number of rules that account for terms being applied to relatives such as a half-sibling. He also pointed out to linguists that kinship was not a unique linguistic domain, as sometimes thought. Anthropologists were discovering parallel, circumscribed domains in ethnobotany, color and disease taxonomies, and even cosmologies.

Since such study identified the components comprising a term, it was known as 'componential analysis.' The procedure emphasized a close relation between linguistics and anthropology, recognizing that cultural content is expressed by language. The search focused on domains in language that could be precisely limited; classification within a domain was determined by discovering the components that

characterized a class. For example, the components that define 'aunt' for an English speaker are: a relative by blood or marriage who is (a) female; (b) two degrees genealogically distant from the speaker; (c) a collateral; and (d) a generation above the speaker. As in denoting contrasting phonemes, 'aunt' can be contrasted with 'uncle' by changing sex of the relative, or with 'niece' if relative generation is varied.

Ward Goodenough demonstrated the method by analyzing Truk kinship terms. Many of his components resembled those of Kroeber, but he discovered others and demonstrated a method that exhausts the components of all kin terms. He argued that the method can also be applied to other linguistic domains. Even color categories, which are classifications along a continuum, can be analyzed for their components, although Goodenough recognized that the significata of the classes are not as precise as those for kin.

Goodenough also concluded that in the domain of kinship, a category is linguistic, not behavioral. Cultural anthropologists generally assume that a kin term suggests appropriate behavior; he warns that 'suggest' is the most a term does. A cultural meaning for 'father' exists in any society that suggests how a father should behave, but fathers often behave in quite contrary ways. It is the components of the kinship term alone that determine who one calls 'father.' Neither the behavior of that person nor the behavior of the 'daughter' or 'son' decide who is called 'father.'

Anthropologists did not ignore behavior, however, in their study of kinship. In an extensive study of contemporary American kinship David Schneider demonstrated its continued importance, despite it no longer being a part of most economic or political life. Kinship remained important in affective relations, and the usage of kin terms was adapting to contemporary conditions. American kin terminology reflected individualism and allowed a wide range of adaptation to many unique situations. In later work, Schneider concentrated on the symbolic value of kinship terminology and its reflection of American values.

Harold Scheffler urged a reevaluation of Schneider's work from a perspective of componential analysis which he believed would correct a view that saw genealogy as relatively unimportant. Schneider noted how 'father' is extended to priests, or 'mother' to the Cub-Scout 'den mother,' as evidence that genealogical distinctions lack relevance. Scheffler dismissed this evidence, seeing it as only a metaphoric extension of a component based on descent.

This debate over kinship terminology illustrated how a behavioral study of kinship could lead one to conclude that genealogy is unimportant as a factor in American kinship. Schneider did present convincing evidence. Scheffler's componential analysis, however,

175

gave a different perspective, illustrating not only that genealogy is a part of American kinship terminology but also that componential analysis can complement the behavioral study of cultural anthropology.

5. Kinship Terminology in the Postmodern Period

By the 1980s, a reaction to the highly systematic construction of meaning in kinship terms had begun, illustrated most vividly in new forms of observing and writing ethnographies. Anthropologists seemed deliberately to avoid parts of culture which were extensively organized with the result that kinship terminologies were ignored.

What has happened is that ethnographers have often concentrated on a particular individual, and in their descriptions have paid unusual attention to the relationship between their informant, who is now called a 'consultant,' and themselves. In writing of this relation, their aim has been to evoke what the other person feels and thinks, often including the author's own feeling and thinking in the process.

The result has been an ethnography that startles or upsets the reader, much as impressionist painters hoped to evoke feelings with their art. Just as the impressionist's scene was of the mundane but often fleeting moment, the postmodern ethnographers record parts of a life that may not be related to any other lives in the other culture. No longer concerned with how representative a biography may be, the post-modern ethnographer makes no attempt to account for systems throughout a culture such as those found in kinship, with its easily collected index, kinship terminology.

The new view offers, instead, the idea that kinship is paradoxical. While terms may persist over generations, the feelings of what it means to be a 'wife' or a 'son' change with each generation and even within a generation. The new writing often captures how a consultant juggles relationships widely within the confines of a kinship term, with that term imposing few limits on thinking and feeling. In this perspective on kinship, it is seen as something not particularly learned but as experienced and thus dynamic, changing quickly in a variety of contexts.

Kinship terminologies are not recorded as systematic, even if kin terms are sometimes reported, because the postmodernist sees fieldwork as a fragmentary experience and so descriptions of the experience are likewise fragmentary. Economic and ritual systems, just as kinship systems, go unnoted. The new method appears to contradict the whole history of the study of kinship, but it is giving new insights into the dynamics of kinship behavior and the possible rapid changes in that behavior.

6. Summary

Kinship terminology has been the subject of anthropology and linguistics for more than a century.

Anthropology has focused on behavior and looked for the causes of kin terms in other parts of culture or in the adaptation peoples make to their environments. Linguists have treated kinship terminology as one domain of language, although at times recognizing it as a special domain. Recognition of kinship terminology as language meant that it was treated as psychological and accepted as a given, without search for causal factors.

Some anthropologists are among those regarding kinship terminology as psychological, as represented by componential analysts and by Kroeber. Some linguists have studied the behavior involved in kinship and looked for its causes. Both approaches have always recognized the systematic nature of kinship, especially as it is recorded in kinship terminology. Postmodernism reflects a major break with this tradition. Concentration is upon fragments of experience with no attempt to record any systems within culture. This work provides no basis for cross-cultural comparisons; indeed, what postmodernists record of kinship within a culture is likely to vary widely among individuals.

The postmodern development contrasts sharply with the century of kinship study that preceded it. The new approach may be a necessary swing of the pendulum against the trend of componential analysis that lost sight of human actors in concentrating only on the language of kinship terminology, but it is hard to see how any scientific endeavor can ignore the system and regularity that is revealed in kinship terminology.

For the future, it appears likely that scientists will return to both the psychological and cultural approaches. Which one will prove superior is unknown, but it is clear that the systematic nature of kinship terminology makes it too attractive to linguists and anthropologists to ignore. The immediate future is likely to see a revived study of kinship terminology as both a domain of language and of culture.

Language in the Workplace

B. Holmqvist and P. B. Andersen

Language associated with a workplace is often classified as a specialist jargon or specific terminology belonging to a specific scientific area or craft. But a workplace is as complex as a whole nation. In this article vocabulary research is disregarded, and a less investigated area, namely 'communication' in work is described. For example (1), exchanges like the following:

A: Are you going to keep that one? (1)
B: I don't know, there was a number I changed that I had to look up in the book. Am I supposed to change it on the list?
A: Piss on it.

Most of the communication in a workplace is of this kind, just ordinary casual talk among fellow workers performing daily tasks; a 'work-language' that is necessary in order to render a service or produce a commodity or to reproduce social relations and values in the working group. Language used in this communication is not primarily characterized by its vocabulary, but rather by its context-dependency (see *Context*).

1. The Workplace as an Empirical Basis for Linguistics

Although communication in organizations has been an object of investigation for quite a time, it has yet to be properly integrated into linguistics and sociolinguistics. Although pragmatics (see *Pragmatics and Sociolinguistics*) and discourse analysis (see *Discourse*) emphasize context and language as action and cooperation, the empirical basis is rather specialised, such as, for example, classroom conversations, or therapeutic or juridical contexts.

There are several good reasons for linguistics to broaden its empirical basis with studies of language in the workplace. Most people spend a considerable part of their life in a workplace. They spend this time in specific work situations that manifest constraints not found in leisure time communication or artificial examples. The work situation highlights the contextual aspect of language since work-language is language usage in a concrete situation.

The action aspect of language is highlighted since in a workplace—more than any other place—one uses language to get things done.

The cooperative aspect of communication is highlighted, since in a workplace, one uses language to get things done in cooperation with others.

The associated work-language may provide partial explanations of the properties of the sociolect if its definition includes the speaker's role in production.

Finally, work-language has considerable practical importance in planning and understanding organizational changes, especially in connection with the introduction of new information processing equipment.

2. Sociolinguistics

From a work-language perspective, some studies of sociolects become problematic. Basil Bernstein's, theories suggest that linguistic codes (see *Code, Sociolinguistic*) are inherited within the family, but then how did the family get its communicative habits in the first place?

Different conditions of work and communicative opportunities can often give quite transparent and down-to-earth explanations of sociolinguistic differences. A good reason for managers and administrative staff to use elaborated code, and for blue-collar workers to use restricted code is that the former are paid to describe absent objects or events,

or classes of them as the manager in the following example (2):

> One of the purposes of the Optical Character (2)
> Recognition is of course that one can read every-
> thing optically—directly, that is—for example our
> pay-in slips 'C'; because they have complete rows of
> optic codes, so they never have to pass the B25.
>
> (Holmqvist 1989)

while the latter are paid to produce the objects, not to talk about them. And when talk is necessary, it will tend to concern present, concrete objects as below (3):

> They code a lot of C-slips that have this optic (3)
> area—the machines are able to read it, and so they
> read the slip and we don't have to touch it—when
> we put it into the frame, the machine reads it and
> then we lift the blue box, and then they are ready.
>
> (Holmqvist 1989)

Work-languages neither coincide with national languages (see *National Language/Official Language*) nor with sociolects. The Volvo plant in Gothenburg provides a good example of this. On the one hand, the Swedish workers in the plant share a lot of morphological, phonological, and lexical forms with other working-class speakers in the city. On the other hand, more than 50 percent of the workers are immigrants who hardly speak Swedish at all; still, they do communicate and make themselves understood in the work situation. In this case, the work-language may comprise several different national languages.

3. Economy and Organization

Economic viewpoints are more relevant in the work-place than elsewhere. The organization can be seen as a network of economic exchanges. Contracts are set up in order to control initiation, execution, and conclusion of these exchanges, and the labor involved in this causes costs. Computerization is seen as one way of reducing communicative transaction costs.

One must ascertain the function of communication before it is changed, in order to avoid unintended difficulties; hence it is important to link work-language with organizational issues. One way to do this is to look at the organizational functions it serves and how it does it: for example, whether language is used to coordinate work, to distribute work, to instruct, or just to keep communication channels intact.

A work-language is dependent upon the type of work organization it is used in. A comparison of a large organization and a small-scale enterprise showed that many of the communicative functions found in the latter were not verbalized at all in the former, and some of them only on rare occasions. This was true of *ordering*, work *coordination*, work *distribution*, i.e., functions concerning the organization of work, and of *control, supervision*, and *reporting*, i.e., control functions. The overall organizational routines took care of this in the form of written schedules and internalized knowledge. But communication types that may seem to be superfluous from an economic point of view (*talk-in-the-work, greetings, comments*), considering only the isolated task, played an important role in reproducing knowledge and social relations in the organization, and were indispensable for its proper functioning.

4. Nonverbalized Meaning

Semantic analysis of work-language must be contextualized, as otherwise one would get a distorted picture of the language.

Classical linguistic analysis bases semantic analysis on some variant of the commutation test. This principle is a sound one, insofar as it prevents setting up meaning units that cannot be empirically justified. However, it presupposes that meanings are verbally expressed, and this presupposition is clearly inadequate in analyzing work-language. If a language is conceived of as a set of latent possibilities that are realized in actual speech, serious methodological difficulties can arise. A work-language researcher will typically be in the situation of understanding only a fraction of the data. Only a thorough knowledge of the work situation enables him or her to interpret it. Noncommunicative acts may substitute for communicative ones: only a part of an utterance is verbalized, the rest being manifested as work; or a work operation may be performed with a secondary communicative purpose, 'telling by showing.' In some coordinative functions, the very structure of the utterances depends upon the work process in which they are embedded. One may say that communicative acts are subordinate to noncommunicative ones as in the following exchange during a car repair (4):

> B: Yes a little further out and up, a little higher up
> towards you—there (4)
> A: Try and hold it
> B: Yes
> A: It's okay
> B: Can I start to screw?
> A: Yes—I think it's there
>
> (Holmqvist and Andersen 1987)

If one associates linguistic analysis closely to the situation type, and define a work-language as a language used *in* a work situation, one can say that the implicit meanings in the conversations between two skilled workers can be observed explicitly in other situations, where language is used *about* the work situation to an outsider, e.g., a novice, a visitor, a superior, etc. In such situations contextual

meanings are verbalized and a comparison between the different situation types makes a catalysis of nonmanifest meanings empirically justifiable.

5. Information Technology

Constructing computer systems implies constructing and communicating an interpretation of the tasks and of the organization in which the system is used. The language users of standardized computer-mediated communication are often distinct from the 'language designers.' This means that the language may cease to be a bearer of the collective experience and identity of the workers.

In the following quotation, two workers are discussing the same system, the topic being the control area of the screen where descriptions of the tasks are displayed (5):

> A: Like, if we say, now it says 'completion' up here, but then, when I finish the pile, then it says 'production,' how come? (5)
> B: Because then you begin a new 'production,' then, when you type, when you have typed the first one and the last one, then it says 'completion.'
> A: Yes.
> B: It always says here exactly what you're doing.
> (Holmqvist 1989)

In this case, A has a different idea of 'what she is doing' than the system. On the researchers direct question A reveals a proper knowledge of the system but ends up referring to the work in a non-computer based, but still new term (6):

> R: You say 'complete,' do you? (6)
> A: Well, but we usually say—*anyway, we call this registering;*

Often workers in fact reject systems terms and spontaneously invent words that for some reason fit better to their conception of the task than the one provided by the system.

While the communicative functions of computer systems are often unambiguous and task related, in work-language, communication types serving to reproduce consensus about past and present events are intertwined with types that are more directly related to actual work, as shown in this exchange during a brake repair (7):

> B: No doubt about it, the drums must be stripped, in any case, we need two new front drums (7)

> A: Oh
> B: This is the worst I have ever seen
> E: You can use them as sandpaper
> A: He has driven long enough with these
> B: I have never seen anything like this before
> A: They are much worse on the other side
> E: There are only the rivets left
> B: Have you ever seen anything like it before
> A: No, not that I know of, it looks very bad
> B: Yes it does, doesn't it?
> A: It'll probably be too thin if it is stripped
> B: It certainly will
> (Holmqvist and Andersen 1987)

Utterances about the bad condition of the brakes are repeated in variations throughout the text. The speakers try to persuade themselves and their colleagues to agree on a certain interpretation of an ambiguous situation. In this situation, work-language is not only *rational* and to the point. It is also a piece of everyday life art.

Although a systems designer should not design the computer based sign system as a copy of the existing work-language, some knowledge of the latter is a good basis for understanding the part of design that has to do with the users' interpretation of the system.

6. Future Work

The growth of information technology entails an increasing interest in language at the workplace. It is a serious challenge for pragmatics to contribute to the future methodological and theoretical development of this emerging field.

A variety of application areas are presented in Holmqvist et al. (1996).

Narrative, Natural
M. Toolan

One of the most significant intellectual and disciplinary shifts within applied language studies of all kinds in the 1970s and 1980s could be summarized as an enlargement of basic analytical resources, beyond the

sentence, to include the story. The decontextualized constructed sentence perhaps remains the chief research instrument of core linguistic areas (especially syntax), a vehicle for probing linguistic knowledge of various kinds. But increasingly researchers in psycholinguistics, sociolinguistics, second-language acquisition, discourse analysis, and pragmatics also use the situated narrative as a research instrument. Situated narratives may be produced spontaneously or in a relatively natural situation (in the context of Western education, even showing three pictures to a child and later asking him or her to recall the story counts as a relatively natural experience for that child). By comparison with other kinds of linguistic data, such narratives, it is held, furnish a less forced or artificial (and so more sociologically and psychologically real) display of language behavior, mental faculties, and whatever else may be involved in cultural and communicative competence. The following sections chart just some of the influential ways in which natural or situated narratives have been studied and used to advance understanding of topics as diverse as cognitive development and covert discrimination in education.

1. Labov and Narrative Structure

A great deal of exciting work on naturally occurring narrative—particularly the narratives of ordinary people in their everyday lives—stems from just two seminal essays by the American sociolinguist William Labov (Labov and Waletzky 1967, Labov 1972). Labov hypothesized that fundamental narrative structures are to be found in oral versions of personal experience—the ordinary narratives of ordinary speakers. Using basic techniques of structural linguistic analysis, Labov sought to relate linguistic–structural properties to functions, isolating two such functions as essential in situated narrative. The first of these is the referential function: narrative is a means of recapitulating experience in an ordered set of clauses that matches the temporal sequence of the original experience. The second is the evaluative function. Here, narrative is expressive of a teller's—and addressee's—involvement with and reaction to a story: the linguistic reflexes, in the narrative telling, that the story is not simply something to be reported in a detached way, but is and was a part of the teller's lived experience. Part of the evaluative function is the standard requirement that a narrative have a point and be deemed, in the given situation, worth telling.

A foundational claim is that fully narrative clauses, the backbone of narrative as defined by the referential function, are temporally ordered independent clauses that must occur in a fixed presentational sequence. It is the potential mobility of subordinate clauses around the main clause from which they depend (without alteration of the basic event

sequence, the story), that excludes them from consideration as fully narrative clauses. The very opposite of a fully narrative clause is typically one describing the circumstances surrounding the fixed sequence of events, moveable to any point in the text, and so known in Labovian terminology as a free clause. Interestingly, mainstream functionalist linguists who do not necessarily subscribe to Labov's proposals are now directing much attention to such questions as what counts, cognitively and linguistically, as an 'event'; how discoursally real are impressions of 'background' and 'foreground,' and what grammatical factors in different languages contribute to backgrounding (e.g., tense, aspect, realization in subordinate clauses); what part in such stagings is played by word-order and, in complex sentences, clause order; and whether there are patterns in the use of discourse anaphora (vs. nonpronominal subsequent mention of an individual in a story), which are sensitive to the discourse-salience of the individual being referred to.

Narrative and free clauses respectively enact the two core functions of narrative: the referential recall of temporally ordered experience, and the evaluative staging of the story so as to convey its point and tellability. Intermediate clause-types, with limited mobility in the text, may be subtle but analyzable and predictable blends of these functions (Labov's names for these include narratively coordinate clauses and restricted clauses).

Labov's scheme really only attracted wider attention when he applied it in the study of a cultural phenomenon of rather more political contention than Propp's Russian fairytales: he used the model to highlight the logic and structure of oral narratives elicited from lower-class young black males in New York City. In Labov 1972 a six-part structure is posited of a 'fully-formed oral narrative':

  (a) Abstract: What, in a nutshell, is this story about?
  (b) Orientation: Who, when, where, what?
  (c) Complicating action: Then what happened?
  (d) Evaluation: So what, how is this interesting?
  (e) Result or resolution: What finally happened?
  (f) Coda: That is the end of the story, the speaker has finished and is 'bridging' back to the present speaker–addressee situation.

Some brief remarks on these numbered elements are in order. Evaluation, while associable with a most expected place in the progression of a narrative (i.e., just prior to the resolution), in practice may well permeate the entire telling, occurring anywhere. Together with the coda, the abstract can be thought of as one of the optional margins of a narrative. Complicating action, on the other hand, the phase in which most of a story's positionally-fixed narrative clauses occur, is the obligatory nucleus. An abstract

may serve three distinct ends: it may sketch a narrative in a severely abridged form (while never being an adequate telling of it); it may constitute the request of an extended turn of talk necessary to tell a story; or it may function as advertisement or trailer for a story.

A variant of the normal pattern in which a single teller provides both abstract and following story is that where a coconversationalist supplies an abstract of a story considered worth the telling, in the process of prompting or inviting another participant to tell it. This technique may appear in many settings where at least two of the participants know each other well, but it is particularly noticeable in the behavior of long-established couples at social gatherings. One interesting consequence of the technique is that worries about tellability are no longer, as usually, directed at one's addressees: the prompter has effectively gone on record asserting the tellability of a story, and the prompted teller has the luxury of proceeding or not (politeness permitting), depending on whether he/she thinks the story tellable. The collaborative story-introduction is, however, fraught with uncertainties over, for example, the willingness of the selected teller to take up the task of narrating, and the acceptability to that teller of the story abstract which has been supplied.

As indicated above, orientation specifies the participants and circumstances, especially of place and time, of the narrative, and is equivalent to what is very commonly called 'setting' in literary discussions. While orientation material can be embedded within opening narrative clauses, it more commonly comes in a block of free clauses prior to the development of the narrative action. Or at least one might think of the position between abstract and complicating action as the unmarked and logical position for orientation. In the orientation, verb-forms can be expected other than extensive verbs (i.e., transitive or intransitive verbs involving action) in the simple past tense. Thus here may be found past perfectives and past progressive verb phrases, and intensive verbs (*be, become, seem,* etc.) in relational clauses specifying attributes and identities. But perhaps the most interesting use of orientation is where components of it are strategically delayed, and the audience is told salient facts about the setting late in a narrative. This, like analepsis, may create effects of considerable surprise, even of shock. It may be particularly used where the teller himself, as participant in a sequence of events, has only belatedly learned some salient facts of a situation and wants to put his audience in a similar experiential position.

2. Evaluation

Evaluation consists of all the means used to establish and sustain the point, the contextual significance and tellability or reportability, of a story. It may take very

many forms and appear at almost any point in the telling, although it is often particularly clustered around the 'hinge' or climatic point of the action, just before—and in effect delaying—the resolving action or event. It is the preeminent constituent by means of which the narrator's personal involvement in a story is conveyed.

The Labovian subtypes of evaluation are first distinguished according to whether they appear inside or outside the fixed-position clauses of narrative. Evaluations appearing outside the narrative clause are of five subtypes:

(a) wholly external evaluation; here the narrator breaks out of the frame of the story-telling to address the listener directly, expressing a current of still-valid general comment on the distant events;

(b) evaluation embedded as a comment reported as made by the teller-as-participant at the time of the events themselves;

(c) a comment made by the teller-as-participant to another participant;

(d) an evaluative comment reported as made by another participant;

(e) evaluative action; how some participant responded in physical rather than merely verbal terms to the ongoing events.

All the above modes of evaluation involve a temporary suspension of the action, a brief 'time out' from the telling of the story proper. When well-placed, such maneuvers do indeed create suspense, set apart whatever narrative follows (often the concluding resolution), and heighten the listener's interest. But all such more external suspensions can be contrasted with the narrative–clause–internal modes of evaluation.

Narrative–clause–internal evaluation is categorized by Labov into four subtypes.

(a) Intensifiers. Here are included gestures (often accompanied by deictic *that*), expressive phonology, exaggerating quantifiers, repetitions, and ritual utterances.

(b) Comparators. These indirectly evaluate, by drawing attention away from what actually happened by alluding to what might have been, what could be, but what does not happen. The main types of comparators are expressions of negation, modulation, and futurity (all encoded in the auxiliary verbal elements), as well as questions, imperatives, and, most overtly, comparative or superlative phrases. All of the above involve an indirect evaluative departure, in the lexicogrammar, from the simple direct telling of the narrative actions. A more complex departure is the use of simile or metaphor in narrative clauses.

(c) Correlatives. These combine events in a single independent clause, and require complex

181

syntax (and are hence often beyond the control of young narrators): progressives (BE + V-ing), and appended participles (adjacent verbs in nonfinite V-ing form), both of these emphasizing simultaneity of occurrence of actions.

(d) Explicatives. These are appended subordinate clauses which qualify, or give reasons for, the main events reported: thus, clauses introduced by *while, although, since, because*, and so on.

A particular attraction of the sociolinguistic analysis of the oral narrative of personal experience is that it seems to underlie the structuring of many literary narratives too. Chapter 2 of Pratt (1977) presents numerous examples of novels and short stories revealing various forms of abstracts and orientations, though usually on a greatly enlarged scale. All sorts of departures from the unmarked or canonical narrative format, with adequate abstract, orientation, and so on, are to be found in literary narratives. Thus many novel- and story-openings project the reader into the flow of events, with insufficient orientational briefing, which may paradoxically function as an assumption of familiarity, or a radical denial of its possibility.

Pratt articulates the important point that no radical gulf divides literary narratives from everyday ones: the same devices, used for the same purposes, operate in both. She concludes:

> What is important about the fact that literary narratives can be analyzed in the same way as the short anecdotes scattered throughout our conversation? To begin with, it casts grave doubt on the Formalist and structuralist claims that the language of literature is formally and functionally distinctive.... Unless we are foolish enough to claim that people organize their oral anecdotes around patterns they learn from reading literature, we are obliged to draw the more obvious conclusion that the formal similarities between natural narrative and literary narrative derive from the fact that at some level of analysis they are utterances of the same type.
>
> (Pratt 1977: 67, 69)

One kind of qualification to Labovian analysis, with its seemingly sharp division of narrative doings from evaluative sayings, is influenced by the work of the philosopher J. L. Austin, and his speech-act analysis of language, according to which use of words in interaction is typically a performing of actions and not merely an asserting of true or false (hence evaluative) statements. (Labov's own informants demonstrate this vividly in other interactions he analyzes: their developed skills of dueling, rapping, and sounding demonstrate how speech itself can perform both complicating and resolutory action.) A more suspicious mode of analysis might also focus more on the degree to which a teller may distort and repress actual events in his or her retelling. Culler (1981: 184–5) notes that in the assumption that there is first a sequence of actions (the narrative) which is

then decorated so as to enhance their point or tellability (evaluation), the possibility of a reverse order of impulses is being ignored, namely that, guided by the prior awareness of the tellability-requirement, tellers' evaluations shape their plots.

3. Stories in Society

Another approach to the evaluations in stories, and to the point of telling them, less directly attentive to linguistic form than Labov, more interested in community-wide motivations, comes in the work of those who try to relate tellability directly to cultural presuppositions and values. Thus in numerous papers Tannen (e.g., 1979) (see *Tannen, Deborah*) shows in some detail how one's 'structures of expectation' based on past experience influence the particular ways one constructs stories, and interprets those of others. This in turn would predict that the kinds of stories that get told, and are valued, in one cultural milieu may differ quite considerably from those that get told in another. Such seems to be the case, not simply when stories and story-points in two quite different societies are compared, but even when contrasting stories and their evaluation between two communities within the same larger society. This was the finding of Heath (1983), in her comparative study of language use in two small-town working-class communities in the rural southeast of the USA, one black and the other white. These two communities reveal quite different views of stories and storytelling, often with neglected educational and intercommunal consequences and misunderstandings (see *Literacy*).

4. Narrative Performance

Over the past few years a number of sociolinguistic studies have appeared using the folkloristic term 'performance' to describe a certain type of particularly involved and dramatized oral narrative. The term has been adopted and espoused despite resistance from some traditional folklorists, for whom the term standardly denotes the retelling of stories that are part of a tradition, are 'collectively' known, and are non-innovative.

The elaboration of the idea that narratives are often performances seems to have first emerged in the work of the Russian Formalist Eichenbaum (in his celebrated analysis of Gogol's 'The Overcoat'), whose concept of *skaz* (the teller-expressive 'yarn') has been highly influential in poetics. Most recently Hymes (see *Hymes, Dell Hathaway*), and Goffman (see *Goffman, Erving*), have advanced the study of narratives as performances, with the fullest socio-linguistic exposition of the issues coming in Wolfson (1982). To 'perform' a story is to furnish one's addressee with a more vivid and involving experience of that story, while exploiting special performance

features as resources for highlighting the story's main point. These performance features include:

(a) direct speech;
(b) asides;
(c) repetition;
(d) expressive sounds;
(e) sound effects;
(f) motions and gestures;
(g) conventional historic present (CHP) (alternating with narrative past tense).

Clearly, many of these are already incorporated in some part of Labov's typology of evaluation devices, and only items (b) and (g) are noticeably new. In an aside a teller exits briefly from the time-reference of the story-dialogue he is recounting in order to add some comment about the content which has continued relevance in the present time of the teller and listeners. Both more innovatory and controversial is the explanation of conversational historic present (henceforth CHP). Wolfson questions the traditional grammarian's view that historic present, in conversation-embedded narratives, is there simply to make a story more vivid and immediate. Historic present, as used in conversation-embedded narration, has a distinct function for Wolfson (hence the emphasis on conversational historic present), and that function relates not directly to the occurrence of CHP itself, but to the patterns of switching between historic past and present tense. The switches or alternations, she says, create three main effects:

(a) an intervention by the teller;
(b) a focusing of attention on certain portions of the narrative; and
(c) a dividing up of the flow of action into distinct events.

These claims have met with some resistance from other theorists. If consistency of tense is proposed as the unmarked option in story-telling, tense-switching clearly becomes marked and noticeable; but other analysts see it as only one of very many mechanisms of teller 'intervention.' Significantly, historic present often appears only in the complicating action of oral narratives—precisely the section of stories where tense does not have to do any special task of temporal orientation (since temporal and presentational order can be assumed to be congruent). The consensus view is that tense-switching is a major potential (but not essential) means of separating out events in narratives, while CHP itself is highly evaluative and addressee-involving.

But a fuller examination of the varying relative weightings of different evaluative devices in narrative is still in progress. Wolfson's work on CHP specifies a number of variable factors which seem to influence a teller's decision to perform or not perform a narrative:

(a) similarity (or not) of sex, age, ethnicity, occupation, status, between teller and addressee;
(b) whether the teller and audience are friends;
(c) the teller's assessment of the audience's similarity of attitudes and background;
(d) whether the speech situation itself is conducive (e.g., the interview situation is not conducive); and
(e) more directly to do with the story itself: whether the story topic is appropriate to the audience, whether the events are recent or not, and whether the story includes physical or verbal interaction or not.

The probing of the influence upon tellers of various performance features taken as a group can evidently be undertaken, in principle, for any other evaluative device or group of devices. But simple trends are not always to be expected—e.g., the greater likelihood of stories to be 'performed' where conversationalists are of the same sex, of similar age, similar status, are similar in attitudes, background, status, and so on. For evaluation undertakes a larger, more crucial task, than that of performance: the task of articulating the point of a story and persuading the audience of its tellability. And where there are few dimensions of similarity between conversationalists, it may transpire that evaluation has a greater role to play, in spelling out the significance of a tale for a teller to a listener who does not share an 'unspoken understanding.' Thus greater rhetorical efforts of displayed evaluation may be involved where interactants are, in fact, remote or unaffiliated in various ways, and lack communicational closeness or mutuality.

5. Diffuse, Embedded, and Group Oral Narratives

There are other types of personal narrative, more subtly interleaved with the ongoing conversation, than those Labov extracted. One variant has been termed the 'diffuse story': here, a portion of a story is followed by an extent of multiparty conversation glossing, clarifying, and amplifying aspects of the story-portion just told. In such a format, story-evaluation can become a collaborative exercise. Diffuse story format shades into practices of embedding where, for example, several short stories are spread out and interrupted by conversational interludes, but can also be treated as the several sections of a single, overarching story.

The group story is in some respects an admirably collaborative and egalitarian storytelling mode, built on a heightened degree of interdependence. The division between tellers and listeners falls away, as does anxiety over tellability, and a spirit of benevolent mutual indulgence may prevail: all are contributing to a story that each already knows. But, in some ways, and with more scope than usual, a competitive rivalry may shape the several contributions to the telling, there may not be full agreement on the point of the story, nor as to who among the teller-participants comes out of the story well, and so

on. In some ways, given the general familiarity with the broad story outlines, the exercise may become more oral-literary, with great attention paid to the most effective and entertaining methods of verbal expression. The group story is an arena where greater fictionality may be tolerated; credibility or vraisemblance is not a prime concern, since focus is less on any particular teller than on the tale for the tale's own sake. The retelling may be for purposes of reminiscence and social binding, with the emphasis less on the incidents themselves than on painting a rich picture of the situation. But again one should avoid being overly stipulative. In practice, a group story may become more a series of hypotheses or conjectures about what might have been the case (the true resolution, the proper evaluation) concerning some set of events, particularly where all the group-tellers were detached witnesses of those events, with limited inside knowledge. And the more that a group's talk becomes an unordered set of overlapping conjectures, the more talk returns from narrative mode to that of ordinary conversation or gossip.

6. The Development of Narratives in Children

Considerable psycholinguistic and sociolinguistic attention has been devoted to the emergence of storytelling and story-comprehension skills in children. The kinds of questions this research addresses include: what kind of competence (linguistic or cultural?) is involved in the child's growing narrative sophistication?; are children's stories best seen as simplified versions of adult ones or less directly related?; how attuned are children to the story models adults give them (e.g., in story books)?; can story complexity be nurtured and accelerated, or is it chiefly a matter of cognitive ability and readiness?; and how is the activity of storytelling best harnessed to broader skills-development in the child, such as learning to read, write, and write in ways appropriate to some constrained task?

In the area of emergent literacy, well-established findings are that invaluable preparation for literacy can begin at home, particularly where the child has there an enthusiastic and supportive interactant attuned to the child's 'prewriting' aptitude. Vygotsky's theory of cognitive development and his notion of a zone of proximal development have been highly influential here, for the older caregiver is in effect assisting the child to occupy each new zone of cognitive and interactive difficulty. One form of this assistance is the use of a teacher–scribe in preschools and kindergartens: the child retains responsibility for formulating the story to be dictated, but the scribe subtly assists with focusing, reminders of the structure and narrative line under way, matters of clarity, and so on. Dictation is in effect 'doing writing without (the physically overwhelming work of) doing

writing.' It also fosters both a degree of detachment from the events of the kind essential to effective story-orientation and reflexive self-awareness. Reading back a dictated story to a child introduces him or her to the possibilities of second thoughts, self-correction, assisted improvement, and objectified verbal production. All this is further enriched and enlarged when dictated stories are subsequently dramatized, and issues of plausibility, vividness, and coherence are raised.

Besides dictation and dramatization, the activity of 'sharing time' or 'share, show and tell' is perhaps the most productive and revealing vehicle in young children's narrative development. But as noted briefly in Sect. 4 above, sharing stories can be problematic, particularly when teacher and children do not, in fact, share a common set of assumptions about what counts as an effective and tellable story. Additionally, and by contrast with the relative intimacy of dictation, sharing time is more dauntingly public narrative production. Heath (1983) vividly shows how even three geographically adjacent American communities have quite different orientations to literacy in general and to narrative in particular, so that the required adjustments to school and schooling have to be quite different in each case (or should be, so as to achieve the educational success to which each community declaredly aspires). One contrast of storytelling styles seems to be that between a 'topic centered style' in which an overtly grounded topic is pursued with copious lexicogrammatical markings of cohesion and coherence, and a 'topic associating style' in which implicit connections are more relied upon, no single topic serves as a foregrounded subject matter, and coherence and evaluation are carried more by rhythm and intonation than by conjunctions, pronouns, and lexis (there are similarities and differences between these styles and Bernstein's (see *Bernstein, Basil*) elaborated and restricted codes (see *Code, Sociolinguistic*)).

In the field of cognitive studies of children's narratives, Piaget's pioneering work (1926) still commands respect. He found, in the story-recall ability of 8-year-olds by contrast with 6-year-olds, that lapses in attention to matters of order, causality, and orientation were far less frequent. Younger children do not adequately encode either the order of story events or cause-and-effect relations, and their 'egocentric' use of pronouns (with all events oriented to the child's spatiotemporal present) led to confusions in their recall of stories. An invaluable study is that of Peterson and McCabe (1983), analyzing structures and content in a large corpus of informally elicited stories from children ranging in age from 4- to 9-years old. Alongside the increasingly common Labov-style story, with a high point and resolution, a less complex chronological structure was found to persist even in the older children's productions:

stories with temporal sequence but little or no sense of contour, resolution, or evaluative point. Again, subjecting the same corpus to an alternative analytic method, that of story grammars, they found that alongside increasingly complex story episodes there was a persistence of certain merely additive sequences—especially reactive sequences, in which a set of conditions causes changes to occur, but without evident planning or goals on the part of any participant. In addition, countless studies have charted older children's growing attention to means of evaluation, story-decontextualization, -elaboration, and -dramatization, and displayed reception of others' stories. Some have seen in these enlarged competences an increasing mastery of metapragmatic and metalinguistic behavior.

Before leaving children's narratives mention should be made of important research, from those applying and developing systemic–functional grammar, on children's achievements and difficulties in mastering the different genres of writing required of them as they enter middle or secondary school. Here it seems that attention has been paid to developing narrative style and internalizing narrative genre, to the neglect of the argumentative and expository styles so much expected in science and social science classes. Systemic linguists see registers or genres such as narrative as complex combinations of lexicogrammatical choice expressing concomitant choices in field, mode, and tenor of discourse. By charting children's developmental grasp and use of these lexicogrammatical choices (most notably, grasp of the linguistic systems of reference and conjunction), these studies can demonstrate the typical child's acquisition of genres through the school years (the 'prenarrative' nondisplaced activity of observing and commenting is superseded by recount style, then personal narrative, then vicarious narrative, and finally, rather later, thematic narrative).

7. Natural Narratives as Naturally Political

A final contemporary corpus of studies of interest are those which analyze narratives in their political context, on the assumption that the linguistic texture of such stories will itself disclose ideologically motivated emphases and omissions and preconceptions—sometimes of a kind sufficiently backgrounded lexicogrammatically as to escape the conscious attention of the socially situated reader (see especially Fowler et al. 1979, Fowler 1991). Such studies go under various names, including critical linguistic (see *Critical Sociolinguistics*), and critical language studies, and have been directed chiefly at newspaper accounts of contentious issues, media narratives about ethnic minorities, stories embedding forms of class and sex discrimination, the narrativized aspects of legal cases, and stories embedded in medical and other institutionalized and professiona-lized interviews or examinations. What most if not all of these discourses have in common, albeit covertly and perhaps barely perceptibly, is some process of assigning responsibility to specified social actors, and so facilitating attributions of blame. Put another way, critical linguistic analysis is often predicated on the existence of an underlying ideologically formed narrative, with known actors and predicted eventual outcome; the assumption is then that, for example, a newspaper's local narratives about industrial action will strive—and show the marks of that striving—to be congruent with the covert master narrative.

While various linguistic features have been examined for the way they may mediate ideological affiliations, the systemic–functional linguistic description (of English) has been particularly drawn upon, since that theory takes as axiomatic that a language is the most powerful form of social semiotic, that the grammar offers plentiful choices among ways of encoding a message, and that such encodings are functionally motivated rather than arbitrary. The approach implies the widespread possibility and practice of narrative discoursal transformation (in a wide, nongenerative sense of the term 'transformation'). Among the narrative textual features particularly traced have been: options in clause transitivity (including ascriptions of agency, affectedness, circumstantial marginality, and admission or exclusion of an individual as a process participant); passivization and agentless passives; nominalization; under- and over-lexicalization, and collocational emphasis; modality; theme and rheme patterns, and thematic structure; naming patterns and covertly evaluative descriptions; grammatical metaphor (see Halliday 1985); and linguistic and ideological presupposition.

Phatic Communion

D. Abercrombie

Language is not by any means always concerned with the communication of thoughts. The conversations which English people hold about the weather, for example, do not as a rule leave the participants any the wiser; only on rare occasions can information be said to have been exchanged. As far as communicating thought is concerned, they get nowhere. Are they then quite pointless? No; a little reflection will show that this kind of use of language has great social value.

Most peoples have a feeling that a silent man is a dangerous man. Even if there is nothing to say, one must talk, and conversation puts people at their ease and in harmony with one another. This sociable use of language has been given the name 'phatic communion.' The anthropologist Bronislaw Malinowski (1923) (see *Malinowski, Bronislaw Kaspar*) created the term, 'actuated by the demon of terminological invention'; and although he was half in joke, the name has caught on. Malinowski defined it as 'a type of speech in which ties of union are created by a mere exchange of words.' It enters the everyday experience of everybody, from the most highly civilized to the most primitive, and far from being useless, this small talk is essential to human beings getting along together at all.

The actual sense of the words used in phatic communion matters little; it is facial expression and intonation that are probably the important things. It is said that Dorothy Parker, the American humorous writer and satirist, when she was alone and rather bored at a party, was asked 'How are you? What have you been doing?' by a succession of distant acquaintances. To each she replied, 'I've just killed my husband with an axe, and I feel fine.' Her intonation and expression were appropriate to party small talk, and with a smile and a nod, each acquaintance, unastonished, drifted on.

Although the sense matters little, however, certain subjects only are reserved for use in phatic communion, and these chosen subjects differ widely among different peoples. Each of the following questions is, in some part of the world, good form when meeting a person:

How are you?
Where are you from?
How much money do you earn?
What is your name?
What do you know?

Some of them, however, would cause deep offence when used in other parts of the world, though in each case the replies required, and expected, are purely formal.

A knowledge of the spoken form of any language must include knowledge of its conventions of phatic communion. Conversation is impossible unless one is equipped with meaningless phrases for use when there is nothing to say, and the language teacher dealing with advanced students will take care to give them command of the necessary formulas and rules governing their use.

The word *phatic* is derived from a Greek verb meaning 'to speak' and, as originally used by Malinowski, his term meant *communion* (the creation of 'ties of union') which is *phatic*, i.e., by speech, While it has been generally adopted, *phatic* has been wrongly interpreted as 'establishing an atmosphere of sociability rather than communicating ideas.' This misunderstanding has given rise to some curious expressions. It is reasonable to speak, as has one writer, of the phatic sharing of emotional burdens, but—in the light of the original use of *phatic*—it is less reasonable to speak of the phatic function of language, while the widespread 'phatic speech' is, from an etymological point of view, as tautological as 'phobic fear' would be.

Politeness

G. Kasper

In ordinary language use, 'politeness' refers to proper social conduct and tactful consideration of others. Politeness in this nontechnical sense contrasts with 'rudeness.' What counts as polite in any given context is socioculturally and historically determined. For instance, the lexical element *li* in Chinese *limao* ('polite appearance') underwent important semantic changes which reflect such an historic sensitivity: in Confucius's writings (551–479 BCE), *li* referred to the slavery-based social hierarchy of the Zhou Dynasty, which Confucius advocated to be restored. The modern concept of *li* was first documented in the book *Li Ji* (attributed to Dai Sheng, ca. 200–100 BCE), where *li* was equated with demonstration of self-denigration and respect for the other person, especially in vertical relationships (Gu 1990). In English, 'polite' dates back to the fifteenth century ('polished'); in the seventeenth century, a polite person was 'of refined courteous manners' (*The Oxford Dictionary of English Etymology*). Politeness was thus associated with the norms of social conduct extant in the upper classes, and this sense of the term has survived in collocations such as 'polite society.' The semantic association of 'polite' with behaviors of the upper classes is even more obvious in German '*höflich*,' French '*courtois*,' Spanish '*cortes*,' all of which are adjectival derivatives of nouns for court (German *Hof*, Fre. *cour*, Sp. *corte*).

Even though the etymology of 'polite' sheds light on its historic and current usage, 'politeness' as a technical term in linguistic pragmatics (see *Pragmatics and Sociolinguistics*) refers to a broader, substantially more democratic concept. Since the object of pragmatic inquiry is linguistic action, 'politeness' as a pragmatic notion refers to ways in which linguistic action is carried out—more specifically, ways in which the relational function in linguistic action is expressed. This is about as far as one can go in identifying a common denominator for the variety of politeness concepts which have been proposed in the pragmatics literature.

1. Politeness Concepts

According to Fraser (1990), four views of politeness can be distinguished. The 'social norm view' is the one reflected in ordinary language use as referred to above. What counts as polite behavior at any given time in different cultural contexts has been codified in manuals of etiquette, from Erasmus of Rotterdam's *De civilitate morum puerilium* (1530) to the latest version of *The Amy Vanderbilt Complete Book of Etiquette* (Vanderbilt and Baldridge 1978). Elias's exploration of the 'civilizing process' (1978) documents vividly how transformations of affect structure were expressed in different behavioral norms extant in European aristocracy from the Middle Ages onwards, e.g., in prescriptions for table manners. Socialization practices testify to caretakers' efforts to train children in socially acceptable conduct, speech included (Clancy 1986, Blum-Kulka 1990).

Scientific conceptualizations perceive politeness as a 'conversational maxim' (see *Conversational Maxims*), as 'face-saving' activity (see below), or as 'conversational contract' (Fraser 1990). The 'conversational maxim view' postulates a Politeness Principle as complement to Grice's Cooperative Principle. The Cooperative Principle regulates conversation whose purpose is maximally efficient transmission of information, i.e., a primarily referential orientation. The Politeness Principle addresses relational goals, serving primarily 'to reduce friction in personal interaction' (Lakoff 1989: 64). The most comprehensive proposal of a Politeness Principle was formulated by Leech (1983). The global statement 'Minimize the expression of impolite beliefs' (p. 81) is elaborated into six 'interpersonal maxims,' as follows:

Tact maxim: minimize cost to other. Maximize benefit to other.

Generosity maxim: minimize benefit to self. Maximize cost to self.

Approbation maxim: minimize dispraise of other. Maximize praise of other.

Modesty maxim: minimize praise of self. Maximize dispraise of self.

Agreement maxim: minimize disagreement between self and other. Maximize agreement between self and other.

Sympathy maxim: minimize antipathy between self and other. Maximize sympathy between self and other.

(Leech 1983: 119ff.)

Less detailed versions of a conversational maxim approach (see *Conversational Maxims*) to politeness have been suggested by Lakoff (1973, 1989), Edmondson (1981), and Kasher (1986).

The 'face-saving view' of politeness, proposed by Brown and Levinson (1987), has been the most influential politeness model to date. Its fundamental assumptions are a Weberian view (see *Social Class*) of communication as purposeful–rational activity, combined with Goffman's concept of 'face' (1967; see *Goffman, Erving*), an individual's publicly manifest

self-esteem. Social members are endowed with two kinds of face: 'negative face,' the want of self-determination, and 'positive face,' the want of approval.

Participants are assumed to adopt as a global interactional strategy 'the diplomatic fiction of the virtual offense, or worst possible reading' (Goffman 1971: 138f), i.e., the working hypothesis that face is constantly at risk. Consequently, any kind of linguistic act which has a relational dimension is seen as inherently face-threatening, and needs to be counterbalanced by appropriate doses of politeness. Brown and Levinson distinguish a number of major politeness strategies, ranging from avoiding the face-threatening act (FTA) altogether, to carrying it out in different guises. Off-record FTAs are performed indirectly; due to their inherent ambiguity, they have the greatest potential for negotiation (including denial). On-record performance of FTAs can be achieved without redressive action ('baldly'), or by adopting either or both of two kinds of redress: positive politeness, addressing the hearer's positive face wants, or negative politeness, addressing negative face wants. Positive politeness strategies emphasize closeness between speaker and hearer by confirming or establishing common ground, or by referring to desirable attributes in the hearer (hence the term 'solidarity strategy,' Scollon and Scollon 1983); negative politeness strategies suggest distance by accentuating the hearer's right to territorial claims and freedom from imposition (referred to as 'deference strategy,' Scollon and Scollon 1983).

The conversational maxim approach and the face-saving view of politeness converge in categorizing certain types of linguistic action as inherently impolite, or face-threatening. They agree furthermore in perceiving politeness as a continuous rather than an on-off phenomenon. Hence, speakers who intend to perform an FTA have to determine just how much politeness is appropriate to counterbalance the disruptive effect of an 'impolite' action. In Leech's model, each of the six interpersonal maxims has an associated set of scales which help establish the requisite degree of tact, generosity, etc. Thus for the tact maxim, the following scales obtain:

> Cost-benefit scale: representing the cost or benefit of an act to speaker and hearer.
> Optionality scale: indicating the degree of choice permitted to speaker and/or hearer by a specific linguistic act.
> Indirectness scale: indicating the amount of inferencing required of the hearer in order to establish the intended speaker meaning.
> Authority scale: representing the status relationship between speaker and hearer.
> Social distance scale: indicating the degree of familiarity between speaker and hearer.
>
> (Leech 1983: 123, 126.)

The corresponding mechanism to assess the severity of an FTA in Brown and Levinson's model adds up the values of three independent variables: (a) social distance between speaker and hearer, (b) their relative power, and (c) the degree of imposition associated with the required expenditure of goods or services (1987: 74ff). All three factors are culturally and situationally defined. Just as for Leech's scales, the assumption is that there is a linear relationship between the values assigned to each factor and the severity of the FTA, and hence the kind and amount of redress required to counterbalance face-threat.

The conversational maxim view of politeness emphasizes enhancement of interpersonal relationships through abiding by 'social regulations' (in the sense of uncodified prescriptive norms), which help minimize friction between participants and thus ensure efficient functioning of social aggregates. By contrast, the face-saving view, rather than resorting to (internalized) socially sanctioned behavioral prescripts, conceptualizes politeness as essentially addressing members' 'individual needs' ('wants'). It is through the reciprocal attribution of face wants and their symbolically exchanged appreciation in the form of politeness strategies that cohesive social ties are maintained and indeed reinforced.

The 'conversational contract view,' proposed by Fraser (e.g., 1990) represents the most global perspective on politeness. Rather than being conceived of as additional to cooperation, such as redress in view of face-threat, polite conduct implies acting in accordance with the requirements of the conversational contract at any given moment of an encounter. At the outset, the terms of the conversational contract are determined by participants' rights and obligations; however, these may change during, and as a result of, the interaction itself. What exactly the current terms of the conversational contract are would depend on each participant's assessment of the relevant contextual factors and of the conversational interchange itself. Acting politely, then, is virtually the same as using language appropriately. In order to distinguish politeness in this broad sense from speakers' deliberate expression of respect and appreciation, Fraser follows Goffman (1971) in referring to this aspect of linguistic activity as 'deference.'

A further conceptual distinction, largely originating in a critique of the face-saving view of politeness (see below), has been suggested. On the conversational maxim and the face-saving view, politeness serves to implement speaker's goals when such goals are face-threatening or involve 'impolite beliefs.' This type of politeness has therefore been referred to as 'strategic,' or 'volitional' politeness, and needs to be distinguished from politeness as 'social indexing,' or 'discernment' (Hill et al. 1986). Unlike strategic politeness, discernment operates independently of

the speaker's current goals. Rather, it represents interlocutors' ascribed and achieved social properties, as these are linguistically encoded in address terms and other forms of personal reference (see Fasold 1990 for overview), honorifics (see *Honorifics*), and speaker/hearer dependent styles of speaking (e.g., Hori 1986). The study of discernment politeness is thus predominantly a sociolinguistic, rather than a pragmatic concern. Yet insofar as social marking is optional, it lends itself to strategic exploitation (e.g., the choice of more or less formal or intimate terms of address). Unexpected deviation from obligatory social indexing gives rise to 'interactional implicatures' about the speaker's covered attitude to the hearer and the message she is conveying (Matsumoto 1989).

2. Politeness: A Universal in Language Use?

The politeness models by Leech, Brown and Levinson, and Fraser aspire to universal validity (see *Pragmatics and Sociolinguistics*). Least problematic is this contention in Fraser's conversational contract approach, because he offers a structural framework for appropriate communication which needs to be socioculturally implemented: the conversational contract does not exist outside specific speech communities and their members.

The conversational maxim approach is more problematic, because no empirical evidence has yet been provided to support the universality of the proposed maxims. Rather, in an application of the conversational maxim approach to mainland Chinese politeness, Gu (1990) hypothesized two of Leech's maxims (tact and generosity) as underlying Chinese interaction; as it turned out, two further maxims (an address maxim and a generosity maxim) had to be added to account for the major normative orientations of Chinese interlocutors. In analogy with the conversational contract view, the level of abstraction at which the universality claim of the conversational maxim view can be sustained appears to be structural rather than substantive: certainly each speech community has a set of normative orientations in accordance with which members organize their verbal interaction. However, just what these norms are will be at variance across cultures. A methodological problem inherent in the conversational maxim approach is the derivation of the maxims. They are neither induced from qualitatively and quantitatively representative data, nor deduced from some basic theoretical construct by means of a rigorous procedure. Intuitively recognizable as they seem to members of the same or sufficiently similar cultures, their formulation remains nonetheless *ad hoc*. Since there is no theory-inherent criterion to delimit the number of maxims, new maxims may indefinitely be added, which represents a violation of a metatheoretical requirement or parsimony.

Brown and Levinson's face-saving approach is the only one which satisfies the criteria for empirical theories, such as explicitness, parsimony, and predictiveness. However, their strong claim to universality has met increasing theoretical doubt and empirical counterevidence. The most serious theoretical concerns center around the semantics of such fundamental categories as 'politeness,' 'face,' and 'face-threat.' As 'face' is closely related to the concept of self (Arndt and Janney 1992), universally valid conceptualizations of 'face' would presuppose identical notions of self across cultures. A review of psychological and anthropological studies (Markus and Kitayama 1991) provides overwhelming evidence to the contrary. Two distinctly different construals of self are suggested, the independent and the interdependent. The independent construal, endorsed by most Western cultures, builds on 'faith in the inherent separateness of distinct persons' (Markus and Kitayama 1991: 226). The interdependent construal, favored by many non-Western cultures, insists on 'the fundamental connectedness of human beings to each other' (ibid: 227). Hence, emphasis on individuals' autonomy and unique configurations of personal attributes and achievements contrasts with concerns about 'social relativism' (postulated by Lebra 1976, for Japanese culture), embracing both attention to participants' relative social positions and reciprocal assumption of emotional responses. Such differential, culturally mediated representations of self form the backdrop against which notions of face are conceptualized by cultural members. A classic account by Hu (1944), examining the historical and then-current notion of face in Chinese culture, distinguishes two face concepts, one referring to the moral character publicly attributed to an individual (*lien* [lian]), the other relating to an individual's reputation achieved through success and ostentation (*mien-tzu* [mianzi]). Neither of these face concepts is compatible with the notion of negative face. Self-concepts and notions of face will have to be emically reconstructed, in order to avoid misleading cross-cultural generalizations and inaccurate causal attributions to (linguistic) behaviors.

Even more problematic for Brown and Levinson's theory is the link between face and politeness. It is a viable working assumption that all cultures have some notion of face, and some notion of politeness. That face necessarily motivates politeness is a much stronger assumption which does not hold up against cross-cultural evidence (Watts 1989). Gu (1990) argues that it is not so much participants' social needs, but their normative orientations which motivate politeness in (mainland) Chinese society. Ide (1989) and Matsumoto (1988) propose that the overriding interactional imperative in Japanese

culture is not to save face but mark place, i.e., to appropriately index social relationships (hence the proposed distinction between discernment and strategic politeness). There are thus fundamental conceptual differences in politeness notions which discourage universalist theories. (See Arndt and Janney 1992 for an historical and systematic critique of universality and relativity in politeness research.)

3. Politeness in Linguistic Action

Brown and Levinson (1987) offer rich evidence for the microstrategies available to implement each of the major strategic choices for carrying out face-threatening acts. Most of the subsequent studies have examined how specific speech acts are realized, within a particular speech community or cross-culturally/cross-linguistically.

For a number of speech acts, finite repertoires of realization strategies, or speech act sets, (see *Speech Act Theory: Overview*) have been identified. For example, for

  (a) requests (Ervin-Tripp 1976)
  (b) apologies (Olshtain and Cohen 1983)
  (c) complaints (House and Kasper 1981)
  (d) compliments (Manes 1983)
  (e) refusals (Ueda 1974)
  (f) disagreement (Sornig 1977)
  (g) chastisement (Beebe and Takahashi 1989b)
  (h) giving embarrassing information (Beebe and Takahashi 1989a)
  (i) corrections (Takahashi and Beebe 1993)
  (j) thanking (Eisenstein and Bodman 1986)
  (k) suggestions (Banerjee and Carrell 1988)
  (l) offers (Fukushima 1990).

Late twentieth-century evidence suggests that the established speech act sets are cross-linguistically robust. Thus for requests, modificatory dimensions include three major levels of directness (direct, conventionally indirect, indirect), measured in terms of distance between locution and illocution; internal modification of the requestive act, by mitigating or aggravating impositive force; and external modification, expressed by 'adjuncts' supporting the request proper. The speech act set of apology consists of an expression of regret, admission of the offense, assumption of responsibility, account, minimizing the offense/responsibility, and offers of compensation (Blum-Kulka et al. 1989). However, cross-cultural and cross-linguistic variation in the performance of linguistic action is manifest in other aspects of politeness investment (see Kasper 1990 for overview).

3.1 The Distribution of Linguistic Action

Some types of linguistic action are carried out more frequently in some cultures than in others. Hearer-beneficial acts such as complimenting and thanking occur more regularly in some Western contexts (e.g., in the USA) than in some Asian cultures (e.g., mainland China), reflecting both the strong positive politeness orientation and reluctance to impose on others in mainstream American culture, on the one hand, and the assumption, in China, that participants act according to their social positions and associated roles and obligations, on the other. Also, hearer-costly acts such as refusals are perceived as being more socially offensive by Japanese and Chinese interlocutors and thus tend to be avoided, whereas it seems more consistent with American interlocutors' right to self-determination not to comply with another person's wishes.

3.2 Politeness Values: Different Strategies

The equation 'the more indirect, the more polite,' proposed by both Brown and Levinson (1987) and Leech (1983), was not supported by empirical evidence. For American English and Hebrew, conventional indirectness, rather than nonconventional indirectness, was shown to be the most polite requestive strategy; next in politeness value were direct strategies in the perception of Israeli raters and nonconventional indirectness according to American raters (Blum-Kulka 1987). In interaction with familiars but not intimates, direct strategies (e.g., imperatives, statement of hearer's future action) are far more acceptable in the Slavic languages, Hebrew, and German than in any of the standard varieties of English examined so far. It has been suggested that directness to speakers of these languages connotes sincerity, straightforwardness, and cordiality (Katriel 1986) rather than imposition on their freedom of action. It must be kept in mind, though, that in these languages direct strategies are often combined with mitigating modal particles, diminutives and other linguistic means which do not alter the direct expression of pragmatic intent but soften impositive force: explicit marking for politeness is thus taken care of by different linguistic expressions, rather than dispensed with altogether.

3.3 Linguistic Implementation of Realization Strategies

Languages differ in the conventionalization of pragmatic force and politeness (pragmalinguistic variation, Leech 1983). For instance, structures questioning the hearer's willingness or future action (e.g., 'will/would you do x') serve to express conventional indirectness in the Germanic and Romance languages as well as in Hebrew, Japanese, and Chinese, but not in the Slavic languages (Wierzbicka 1991: 32ff, 204). Repertoires of polite formulae index recurrent social events which are most efficiently handled by language-specific prefabricated routines (see *Formulaic Language*; Coulmas 1981). It is part of the pragmalinguistic knowledge shared by members of a speech community to

recognize the contextual distribution of such frozen forms, whereas they do not usually have an awareness of the semantic structure of politeness routines. Since such formulae encapsulate events which require routinely conveyed politeness, they provide pragmaticists with a window to a speech community's value structure and notion of politeness.

3.4 Choices from a Speech Act Set

The strategies composing specific speech act sets, and global modificatory dimensions such as indirectness, minimization, and maximization of pragmatic force (House and Kasper 1981) have been demonstrated to be valid across the languages and communities studied so far. Yet, the selections participants make from such repertoires vary between speech communities, and these variations systematically reflect different cultural orientations. Chinese speakers in the People's Republic not only compliment less, but also on different attributes, compared to English speakers in the USA. Thus, physical attractiveness is not regarded a suitable topic for public praise by most Chinese people (Hsu 1981: 2). Danish interlocutors were found to invest more effort into supporting their requests by justifications than native speakers of English and German (Faerch and Kasper 1989). Ritual refusal of offers and invitations is required in Chinese culture (Gu 1990), but not everywhere else. Americans have a greater proclivity to preface corrections with positive remarks than Japanese speakers (Takahashi and Beebe 1993) and to maximize compliments, both of which reflect a positive politeness orientation. In refusals, Japanese and Chinese speakers use proverbs and philosophical statements more often than speakers in the USA. These generalizations, extracted from databased studies, are, of course, somewhat risky. They represent cultural trends rather than predictions of the politeness investment afforded by individual members of each speech community, and apply only under comparable conditions (see Blum-Kulka et al. 1989). This leads to the final source of cross-cultural variability.

3.5 Contextual Variation in Conveying Politeness

Brown and Levinson (1987) and Leech (1983) proposed a positive correlation between the weight of contextual factors (social distance, power, and imposition) and politeness investment. This hypothesis has not been confirmed by evidence. Wolfson's (1989) analysis of a number of speech acts, performed in a US East Coast middle-class community, demonstrates that intimates use the same politeness patterns as status unequals and strangers. Non-intimates such as status-equal friends, co-workers, and acquaintances invest the most politeness, which is taken to be reflective of the high relationship negotiability extant in such interlocutor constella-

tions. Wolfson referred to this pattern as the 'Bulge Theory' (see Boxer 1992).

The impact of contextual factors on expended politeness varies intra- and interculturally. Each of the proposed factors represents a composite construct which needs to be culturally and contextually elaborated. Social power includes factors such as speakers' and hearers' relative positions in institutional hierarchies (workplace, family), age, sex, as well as acquired and ascribed personal attributes (which have as yet been entirely overlooked in politeness research). Intraculturally, the weight, of each factor might vary contextually, e.g., in many Western contexts, age may be important in personal interaction but not at the workplace, where it may be superseded by seniority. Interculturally, age matters more among most Asian interlocutors than to most Westerners, for instance, among participants in equivalent positional roles. Sex was identified as determining the amount of complimenting and apologies received by New Zealand interlocutors, women receiving consistently more (mostly from other women, see Holmes 1988). Comparing politeness in requests, students in the USA were found not to vary politeness according to sex role relationships, whereas Hispanic students were more polite towards the other sex (Rintell 1981). Different positional roles in institutional hierarchies (university, workplace) alter the politeness investment of American and Japanese interlocutors; however, the Japanese vary their politeness strategies more dramatically, depending on whether speaker or hearer is the superior in status (Beebe and Takahashi 1989a).

The specification of 'imposition' is tied to the linguistic act and the event to which it refers. For apologies, a variety of studies has found that severity of offense is the decisive factor, subsuming obligation to apologize and likelihood of apology acceptance (Bergman and Kasper 1993). For requests, options for different strategies selected by German speakers were hearer's ability and willingness, required urgency, and legitimacy (whether the requestive goal entails compliance with the requester's contractual rights or a favor granted by the requestee (see Hermann 1982)). Of these factors, urgency was *not* found to be operative in Japanese request realization (Morosawa 1990). Asked to evaluate the same requestive contexts, Israelis, Germans, and Argentinians differed in their perceptions of interlocutors' rights and obligations, likelihood of hearer's compliance, and speaker's sociopsychological difficulty in carrying out the request.

Finally, rather than estimating costliness, or face-threat, as the summative effect of contextual variables, it has been proposed that the 'discourse domain' (see *Discourse*) overdetermines what counts as polite, and provides a functional explanation of politeness. In the context of a 'backstage event' such

191

as family dinner conversations, directness functions as enhancement of intimacy and strengthens affective bonds (Blum-Kulka 1990). The public character of legal trials symbolically sets the courtroom apart from ordinary interaction, whereas the solidarity politeness adopted by therapist and client in psychotherapy emphasizes the intimacy required for sanction-free self-disclosure and confrontation (Lakoff 1989). Yet even within a given discourse domain, politeness can vary, even if none of the contextual factors mentioned above alters its value. Studies of different work contexts have shown that politeness may be drastically reduced due to 'real-world exigencies' (Fraser and Nolen 1981), such as problematic flight conditions (Linde 1988), instant surgery (cf. the movie *M.A.S.H.*), or Alpine mountaineering (Moretti 1989).

The complex research program to be addressed by future politeness studies is not only to specify and examine the relationship between contextual variables and discourse domains. Such research will also have to uncover how the ongoing discourse itself constitutes, maintains, and alters participants' rights and obligations, increases and reduces distance, fosters liking and disliking, and so forth. Politeness will therefore have to be studied not only as a dependent variable but as a major force in shaping human relationships.

Speech Accommodation

H. Giles

Accommodation is the adjustment of one's speech or other communicative behaviors vis-à-vis the people with whom one is interacting. Communication accommodation theory (CAT) is a framework designed to explore accommodative phenomena and processes, and in its early years was concerned with the antecedents and consequences of shifting one's language variety towards or away from another, called speech convergence and divergence, respectively (for a recent review see Shepard et al. 2001). Whether verbal or nonverbal, some accommodative processes can have profound social implications. For instance, satisfaction with medical encounters and patients' willingness to comply with crucial medical regimes can be influenced by doctors' attempts to accommodate to patients' speech norms (see *Doctor–Patient Language*). Other examples include reactions to defendants in court and hence the nature of the judicial outcome, job satisfaction, and hence group productivity. There are many ways of performing accommodative acts, many reasons for so doing, with some beneficial and others detrimental to one or more participants. Such complexities will be introduced as will more recently developed discoursal elaborations.

1. Convergence

The extent and frequency of interpersonal convergence has been demonstrated across a plethora of linguistic/prosodic/nonverbal features (e.g., speech rate, pausal phenomena, phonological variants, smiling, and gaze) and in many Western and Eastern languages besides English. Indeed, the ubiquity of this phenomenon (which goes under various nomenclatures in different theoretical traditions, e.g., 'listener-adaptedness,' 'synchrony,' 'congruence') is

so well-recognized that a number of scholars have considered it to be a universal. Indeed, data suggests that it emerges very early on in a child's social life.

1.1 Convergence Distinctions, Motives, and Evaluations

Descriptively, convergence can be labeled: (albeit value-ladenly) 'upward' or 'downward' depending on the relative sociolinguistic status of the convergee; 'full' or 'partial' (e.g., a shift from one's idiosyncratic speech rate baseline of say 50 words-per-minute to match a target's 100 words exactly versus accelerating to just 75 words-per-minute) or even 'cross-over' (in this case an overshoot to 120 words or hypercorrection beyond a standard user's dialect to more exaggeratedly prestigious forms); and 'symmetrical' or 'asymmetrical' (i.e., whether both speakers are, or only one participant is, converging). Most of the studies of this genre are laboratory-controlled investigations, yet many have emerged in more naturalistic settings. Examples are a demonstration of John Dean's convergence of median word frequencies to his Senate interrogators in the Watergate trials and a British travel agent's convergence of phonological variants to her socioeconomically diverse clients.

CAT proposes that speech convergence reflects a speaker's or a group's need (often nonconscious) for social integration or identification with another. It has been argued, and often found, that increasing behavioral similarity (or put another way, reducing dissimilarities) along communicative dimensions in social interaction is likely to increase speakers' perceived (a) attractiveness; (b) predictability and supportiveness; (c) level of interpersonal involvement; (d) intelligibility and comprehensibility; and (e) speakers' ability to gain their listeners' compliance. A variety of studies have shown speech convergence (over speech maintenance from interpersonal context to context) to have been positively evaluated on certain dimensions, both cognitive and affective as in (d) and (a) above, respectively. The first of these, in Montreal, showed that the more effort in convergence a speaker was perceived by recipients to have made (e.g., in this case the more French was used by English–Canadians when sending a message to French–Canadians), the more favorably that person was evaluated and the more these same listeners would converge back in return. Convergence, therefore, is considered a reflection of an individual's desire for social approval: if people are cognizant of (and/or have experienced in the past) positive outcomes from convergence then this is sufficient grounds to consider that an approval (or perhaps instrumental) motive may often trigger it. Not surprisingly then, the power variable is one that is endemic to accommodation research and has surfaced regularly in ways that support CAT's central

predictions. As but one example, a study of code-switching in Taiwan found that salespersons converged their dialects more to customers than viceversa, as customers hold more of the economic reins in these commercial settings.

CAT recognizes however, that convergence is not always evaluated favorably by recipients, or by bystanders, and such occasions would include those when the convergent act is (a) nonetheless a movement away from valued social norms (e.g., converging to a nonstandard interviewer but in a formal job interview); (b) attributed with suspicious intent (e.g., to machiavellianism); (c) attributed by eavesdroppers as a betrayal of ingroup identity when the recipient is an 'outgroup' member (e.g., children in class seen by their peers to adopt the teacher's language style when talking to him or her); and (d) at a magnitude and/or rate beyond which recipients feel are sociolinguistic optima.

1.2 Sociolinguistic Origins and Beyond

The convergence construct was developed originally, in part, as a foil to the then *Zeitgeist* of norms being modeled as the determinants of speech diversity. The first publications in this tradition emerged in 1973 when the present author demonstrated the phenomenon of interpersonal accent convergence and introduced his 'accent mobility' model. Therein he also critiqued some aspects of the original Labovian paradigm. For example, interviewees' casual speech, it was argued, may have been produced not so much because of any informality of the context per se but, perhaps more precisely, because the commanding interviewer (equally prone to sociolinguistic forces) had shifted himself to less standard forms when he introduced certain topics (e.g., being near death) and when the interview was supposedly over (i.e., the tape-recorder was supposedly turned off). In other words, the normative supposition that context-formality determined phonological prestigiousness could be supplanted by an interpretation in terms of a mechanism of interpersonal influence—interviewee convergence to the interviewer. This then was the legacy of CAT. Since then, theoretical refinements have come in profusion and have intermeshed with empirical developments as well, not least of which has been CAT's recognition in the domain of language change (Trudgill 1986). The mechanics of such day-to-day interpersonal convergences in important social networks are the breeding ground for longer-term shifts in individual as well as group-level language usage. Indeed, much of the literature on long- and mid-term language/dialect acculturation can be interpreted in convergence terms (see also Sect. 2 on divergence below) where immigrants often seek the economic and social advantages (as well as costs in some instances) that linguistic assimilation sometimes brings.

2. Divergence

Divergence has received relatively less empirical, albeit not less theoretical, attention and refers to the ways in which speakers increase perceived dissimilarities of speech and nonverbal differences (see Giles and Wadleigh 1999) between themselves and others. Like convergence, it can take on many forms (e.g., upward/downward; full/partial; symmetrical/asymmetrical) and there may be a hierarchy of divergent strategies available to speakers from perhaps the emphasis of a few ingroup stereotyped phonological features and lexical items to abrasive humor, to verbal abuse, to language switches, to interactional dissolution. To the extent that divergent strategies are adopted probably more often in situations where the participants derive from different social backgrounds, the incorporation of ideas from sociopsychological theorizing about intergroup behavior and social change provides an important influx of ideas. From this stance divergence is deemed a tactic of intergroup distinctiveness of individuals in search of a positive social identity. By diverging one's communicative style (e.g., slang, work/sports jargon, grammatical complexity, posture and gait, accent), members of an ingroup can accentuate the differences between themselves and a relevant outgroup on, usually, a highly valued dimension of their group identity. In some cultural contexts like Wales, encounters have to be construed in very 'intergroup' terms for, in this case, bilingual Welsh people even to anticipate diverging away from an English person (by using the Welsh language or even using some Welsh words and a Welsh accent in English). Indeed, for this to happen the latter have to threaten directly core elements of Welsh speakers' cultural identity to which they are strongly committed.

A number of studies of impression formation have shown that the transsituational maintenance of a speech style and divergence are often seen by its recipients as rude and hostile—unless, that is, it can be attributed situationally to extenuating circumstances (e.g., the speaker is known to be extremely fatigued or under stress) and/or the adherence of valued conversational norms (e.g., the speaker moves to a prestige language variety when being very formally interviewed for an executive position by a nonstandard speaker). At the same time, onlookers may react very positively to a member of their ingroup diverging from an outgroup member in a public competitive situation. It is little wonder then that the divergence aspect of CAT has been developed theoretically further into domains of second language learning and language maintenance and death (see Giles and Coupland 1991). Relatedly, increasing accentuation of ethnic speech markers in the recorded Hebrew singing of certain Arab-speaking Jews over a particular historical period covaried with the increasing vitality of that group over the same time. But not all divergences need be intergroup in nature as they can signal personal disdain regarding another's dress, mannerisms, habits, arguments, and so forth. Moreover, and as with convergence, its motivational origins need not always be affective and allied to facework or the maintenance or creation of a social identity. Rather, it may function more cognitively so as to provide a mutually understood basis for communication and to facilitate the coordination of speech patterns. As an example, divergence may be strategically employed to bring another's fast speech rate down to a more acceptable and conversationally comfortable level fostering thereby better comprehensibility.

3. Further Distinctions

Archetypal convergence would occur when the speaker intends to converge linguistically to another, the linguistic movement is measured objectively as indeed having happened that way, and the psychological climate attending it in both speaker's and receiver's eyes is one of interpersonal association. Similarly, classic divergence would be where the speaker wishes to diverge subjectively from another, the linguistic movement is measured as actually having happened as intended, and the psychological climate is perceived by both participants as being dissociative. However, such ideals do not always eventuate as intended and in any case the situation is far more complex and a few complications will be introduced here.

3.1 Converging as Divergence and Diverging as Convergence

First, perceptions of one's own and others' speech can be grossly biased and stereotyped such that one sometimes does not hear people sound the way they actually are. Hence, people may assume they are moving towards where they believe others are, with this often being in complete contrast to where these targets actually reside or alternatively where they think they are located linguistically. For example, Chinese-Thai bilingual children sometimes use Chinese phonological features when talking with an (objectively) standard Thai speaker who looks ethnically Chinese—arguably an instance of miscarried convergence which amounts to actual divergence. Similarly, some native English Australian speakers mismanage their downward convergent attempts toward what they believe (somewhat erroneously) Singaporeans and Aborigines sound like. Misattributions and misunderstandings under these circumstances can of course be potentially rife.

Second, sometimes moving closer to another person psychologically is managed by diverging from them given the social meanings attending the linguistic outcome. This can often occur in role-discrepant situations and has been labeled, 'speech

complementarity.' For instance, some young American women sound more 'feminine' (e.g., higher and more variable pitch) when talking to an intimate, as opposed to an unknown, male over the telephone. CAT also provides—in the context of the multiple goals so often embraced in social interaction and even during single speech acts—for the possibility that convergence, divergence, and even complementarity may be encoded simultaneously but with respect of course to differing linguistic and nonverbal features. Indeed, it has been argued that a fine meshing of physician convergence and complementarity is essential for patient satisfaction and compliance to health regimes.

Third, and conversely, sometimes moving away from another psychologically is managed by converging towards where she or he is believed to be located linguistically. For instance an accommodation norm emerged in Catalonia in the early 1980s dictating that 'Catalan should be spoken only between Catalans.' Then, Castilians who accommodated Catalan speakers with their language would more than likely be responded to in Castilian. In an attempt to structure the foregoing and beyond, Thakerar et al. (1982) formulated a three-dimensional model of accommodation wherein a complex range of logical possibilities, including the above-mentioned, exist. This theoretical position is the sociopsychological heartland of CAT as emphasis is placed on what participants believe they are doing accommodatively and how language strategies help situational definitions and redefinitions rather than on what comprises the linguistic constituents of convergence and divergence.

3.2 Attuning, Discourse, and Health Care

More sociolinguistic infusion, however, was soon to be rendered with Coupland et al. (1988) not only broadening the scope of strategies invoked by CAT, but doing so in ways that embraced a discoursal perspective in a gerontological context. Thus far, the focus on recipients, the audience, or addressees has been on speakers' perceptions or expectations of the latter's communicative performance or patterns of production. With this in mind, Coupland et al. termed the foregoing convergent, divergent, and complementary acts as 'approximation strategies' arguing that they were but one subset of 'attuning behaviors,' the complete class of which, together with enriched addressee foci, better represented the spirit of CAT thinking.

Three additional attuning strategies were proposed. First, an alternative addressee focus to recipients' productive performance was their interpretive competences. Sometimes, as sadly with the case of certain older folk, such competences are stereotyped deficiently in terms of a presumed impaired facility to comprehend. Accommodating

in this case could lead to 'interpretability strategies' so as to reduce complexity, increase clarity, and within set topic boundaries (e.g., by decreasing lexical diversity, increasing vocal amplitude). Second, another addressee focus was recipients' conversational needs which can lead to a wide range of 'discourse management strategies' aimed at facilitating, to varying degrees, partners' interactive accomplishments (e.g., by offering turns, back-channeling, repairing, maintaining other's face). The final addressee focus in this framework was recipients' social roles which would lead to a set of 'control strategies' wherein, say, status discrepancies can be accommodated and the floor, for example, given over to a new junior faculty member in a committee meeting.

High attuning then, caveats above notwithstanding, can reduce sociolinguistic distance between interactants and bring them psychologically closer and facilitate conversational smoothness. Naturally enough, counterattuning can likewise fulfill the same functions and attract the same consequences as classic divergence; other possibilities such as under- and overaccommodation have been explicated. Empirical work largely derived from this attuning elaboration has led to some important new insights into applied social domains including the medical, organizational, and legal, as manifest in some of the chapters of Giles et al. (1999) and in the Williams et al. (1999) collection. Relatedly, it has been claimed that accommodative discourse may be integral to being socially supported—a process deemed vital to psychological wellbeing and physical health. Indeed, feeling supported can be a function of the extent of attuning one receives—with those known to possess attuning skills being sought out as preferred supporters. That said, attuning may not always covary with offering support or feeling supported. Indeed, high attuning can be *non*-supportive behavior where familial security and empathy encourages overdependence and lack of autonomy. Similarly, there may be occasions when long-term support is engineered through counterattuning where indulgences and habits are denigrated, albeit with socially constructive intent and form. Many exciting challenges for a future empirical research program are held out by CAT being grounded in emotional, health, and social network possibilities.

4. Epilogue

CAT has developed its potential as an interdisciplinary heuristic since its self-appellation of an 'embryonic' framework in the 1970s. It has been robust enough to sustain radically different methodologies, become far less alinguistic, and even begun to examine some of the ideological structures underlying certain of its own attuned acts—a kind of meta-accommodation. Put another way, it has developed theoretically at many levels significantly beyond the

concepts and stances which were its precursors and independently derived peers. It is uniquely able to attend to (a) social consequences (attitudinal, attributional, behavioral, and communicative), (b) macrosocietal factors, (c) intergroup as well as interpersonal variables and processes, (d) discursive practices in naturalistic settings, and (e) individual lifespan language shifts and community-wide language change. Doubtless some skeptics claim, divergently, that the theory has been repeatedly 'massaged' to meet the ever-increasing demands of complex, situated, and sequential acts to the extent it is no longer a testable theory—if it ever was one. CAT has, however, been summarized a number of times in propositional format (e.g., Gallois et al. 1995), therein formalizing hypotheses about the antecedents, correlates, and consequences of attuning, and thereby devising a parsimonious and predictive model allowing for falsification. This is not the context to set up defenses but rather to underscore the fact that accommodation theorists have always welcomed and confronted constructive criticism as well as been eager to reach out hands to other related paradigms (see introduction in Giles et al. 1991). Much still needs to be achieved, such as studying the relationships between multiple perceived goals and attuning; the specification of which language and nonverbal features are contextually implicated accommodatively and which are not and why; a more precise analysis of which evaluative and attributional dimensions (and accounting parameters) are associated with what kinds of attuning and when; and programmatic application of relevant aspects of the theory to other communicative modes besides the oral including telecommunications and computer-mediated communications (see Giles and Ogay in press). However, given the level of debate and constructive criticism, innovative research, and more sophisticated theory and applications in crucial social contexts across cultural boundaries so far generated by CAT, it seems likely that it will continue to be a resource for much-needed collaboration between social psychologists and sociolinguists (Meyerhoff 1998).

Speech Act Theory: An Overview
K. Allan

1. The Speech Act as an Aspect of Social Interactive Behavior

A speech act is created when speaker/writer S makes an utterance U to hearer/reader H in context C. Speech acts are a part of social interactive behavior and must be interpreted as an aspect of social interaction (cf. Labov and Fanshel 1977: 30). In the words of Habermas (1979: 2), S utters something understandably; gives H something to understand; makes him/herself thereby understandable; and comes to an understanding with another person. Habermas indicates further requirements on S: that S

should believe the truth of what is said, so that H can share S's knowledge (cf. Grice's 1975 maxim of quality; see *Cooperative Principle*); S should 'express his/her intentions in such a way that the linguistic expression represents what is intended (so that [H] can trust [S])'—compare Grice's maxims of quantity and manner; S should 'perform the speech act in such a way that it conforms to recognized norms or to accepted self-images (so that [H] can be in accord with [S] in shared value orientations)' (1979: 29). Additionally, S and H 'can reciprocally motivate one another to recognize validity claims because the content of [S's] engagement is determined by a specific reference to a thematically stressed validity claim, whereby [S], in a cognitively testable way, assumes with a truth claim, obligations to provide grounds [,] with a rightness claim, obligations to provide justification, and with a truthfulness claim, obligations to prove trustworthy' (Habermas 1979: 65).

2. J. L. Austin

Interest in speech acts stems directly from the work of J. L. Austin, and in particular from the William James Lectures which he delivered at Harvard in 1955, published posthumously as *How to Do Things with Words* in 1962 (revised 1975). Austin came from the Oxford school of 'ordinary language philosophers,' which also spawned Geach, Ryle, Strawson, Grice, and Searle. It was intellectually engendered by Wittgenstein, who observed (e.g., 1963: Sect. 23) that logicians have had very little or nothing to say about many of the multiplicity of structures and usages in natural language. Austin's concern with speech acts exhibits an informal, often entertaining, philosopher's approach to some uses of ordinary language.

Austin insisted on a distinction between what he called constatives, which have truth values, and performatives which (according to him) do not (cf. Austin 1962, 1963). The distinction between truth-bearing and non-truth-bearing sentences has a long history. Aristotle noted that 'Not all sentences are statements [*apophantikos*]; only such as have in them either truth of falsity. Thus a prayer is a sentence, but neither true nor false [therefore a prayer is not a statement]' (*On Interpretation* 17a, 1). Later, the Stoics distinguished a judgment or proposition (*axiōma*) as either true or false whereas none of an interrogation, inquiry, imperative, adjurative, optative, hypothetical, nor vocative has a truth value (cf. Diogenes Laertius 1925: 65–68). For more than two millennia, logicians and language philosophers concentrated their energies on statements and the valid inferences to be drawn from them to the virtual exclusion of other prepositional types (questions, commands, etc.). Austin was reacting to this tradition (cf. Hare 1971: ch. 6):

The constative utterance, under the name so dear to philosophers, of *statement*, has the property of being true or false. The performative utterance, by contrast, can never be either: it has its own special job, it is used to perform an action. To issue such an utterance *is* to perform the action—an action, perhaps, which one scarcely could perform, at least with so much precision, in any other way. Here are some examples:

I name this ship 'Liberté.'
I apologise.
I welcome you.
I advise you to do it.

(Austin 1963 22)

Austin's point is that in making such utterances under the right conditions, S performs, respectively, an act of naming, an act of apologizing, an act of welcoming, and an act of advising (it has become usual to speak of 'acts' rather than 'actions'). Performatives have 'felicity conditions' (see Sect. 5 below) in place of truth values. Thus according to Austin, (1) has no truth value but is felicitous if there is a cat such that S has the ability and intention to put it out, and infelicitous—but not false—otherwise:

I promise to put the cat out. (1)

This contrasts with (2), which is either true if S has put the cat out, or false if not:

I've put the cat out. (2)

Austin's claim that performatives do not have truth values has been challenged from the start, and he seems to be wrong. Roughly speaking, their truth value is less communicatively significant than what Austin called the 'illocutionary force' of U. He observed that utterances without performative verbs also perform speech acts, for example, (3) can be used to make a promise:

I'll put the cat out. (3)

Austin would say that (1) and (3) have the same illocutionary force of promising; the function of the performative verb in (1) is to name the 'illocutionary act' being performed. In the later lectures of Austin (1962), he identified two other components of a speech act: locution and perlocution. Linguists recognize three acts which Austin conflates into his locutionary act.

3. The Hierarchy Within Speech Acts

Speaking (and writing—which will from now on be properly included under 'speaking' for simplicity of exposition) comprises a hierarchy of acts. To begin with, language only comes into existence if someone performs an 'act of utterance.' People recognize utterance acts on the basis of brute perception: by hearing them spoken, seeing them signed or written,

198

feeling them impressed in braille. Individuals can readily recognize an utterance act in a language that is completely unknown to them, in which they cannot distinguish the words or sentences used. One can utter sounds which have nothing to do with language.

Speech act theory is concerned with utterances where S utters a language expression and thereby performs a 'locutionary act.' Performing a locutionary act, S uses an identifiable expression E from language L (where E is a sentence or sentence fragment) spoken with identifiable prosody Φ (the pattern of pause, pitch level, stress, and tone of voice; its counterpart in the written medium is punctuation and typography). The consituent structure of E and of Φ, together with their proper senses (meanings), are also identifiable to a typical fluent speaker of L. Recognizing the locution means recognizing that E spoken with prosody Φ means ' ...': consequently, a locution is produced and then recognized by someone who has knowledge of the grammar, lexicon, semantics, and phonology of L.

S uses the senses of language-expressions in the locution (E and its constituents) to identify things in the particular world that s/he is speaking of. This constitutes the 'propositional act of referring' or 'denotational act.'

The final act in the hierarchy of speaking is the 'illocutionary act.' S *does* something in uttering U to H in context C, for example, states a fact or an opinion, confirms or denies something, makes a prediction, a promise, a request, offers thanks or an invitation, issues an order or an umpire's decision, gives advice or permission, names a child, swears an oath. Thus U is said to have the 'illocutionary force' or 'illocutionary point' of a statement, a confirmation denial, a prediction, a promise, a request, and so forth. Obviously, under normal conditions of use, S makes an utterance, use a locution, denotes with it, and expresses at least one illocution, all at one and the same moment.

With very few exceptions, the purpose of speaking is to cause an effect on H (Austin described this as 'securing uptake'): speakers want their opinions to be recognized if not adopted, their assertions to be agreed with, their requests to be enacted, questions answered, advice taken, warnings heeded, commands complied with, thanks appreciated, apologies accepted, and so forth. These are called 'perlocutions' or 'perlocutionary effects.' The perlocutionary effect of U is the consequence of H recognizing (what s/he takes to be) the locution and illocutionary point of U—otherwise the effect is *not* perlocutionary. Although extremely significant within a theory of communication, perlocutionary acts/effects fall outside of linguistics because they are not part of language per se but instead responses to the illocutions in utterances. What linguists can properly look at, however, are the intentions of speakers to bring about certain perlocutionary effects; these intentions appear in definitions of speech acts as 'illocutionary intentions' or 'perlocutionary intentions.'

4. The Speaker's Reflexive-intention; Hearers, and Overhearers

In the spoken medium, there is never more than one S per utterance; however, two S's may utter identical U's in unison or S may speak on someone else's behalf. Coauthors generally take joint responsibility for what is written; but, normally, each writes only a part of the text. This all starkly contrasts with the number of H's which any given S may have for an audience.

H is anyone whom, at the time of utterance, S reflexively intends should recognize the illocutionary point of U. There are a couple of explanations to interject here. The simpler one is that the illocutionary point of U is S's message. The second point is that S tailors U to suit H, taking into account what s/he knows or guesses about H's ability to understand the message which S wants to convey. The notion of a reflexive-intention is S's intention to have a person in earshot recognize that S wants him/her to accept the role of H and therefore be the/an intended recipient of S's message and consequently react to it. This, of course, renders the definition of H circular, and so something closer to Grice's (1957, 1968, 1969) original proposal should be considered, adapted to our customary terminology and with some updating from Recanati (1987: chap. 7): S's reflexive intention toward H is the intention to have H recognize that when uttering U in context C, S intends that U have a certain perlocutionary effect on H partly caused by H recognizing that S has the intention to communicate with him/her by means of U. (So, when Joe hears Sue talking in her sleep, he will not assume she has a reflexive-intention toward him, and therefore not expect that she intends her utterance to have any perlocutionary effect on him—though she might unintentionally keep him awake.)

Clark and Carlson (1982) distinguish between H as 'direct addressee' and H as 'ratified participant,' the latter being a member of the audience participating in the speech act (cf. Goffman 1981: 131). The notion of face (Brown and Levinson 1987; see *Politeness*) is useful in distinguishing between two kinds each of H's and overhearers. An 'addressee' is someone who cannot reject the role of H without serious affront to S's face. Direct address is determined contextually—by direction of gaze, pointing a finger, touching an arm, using a name, or on the basis of who spoke last; less commonly, the nature of the message will determine who is the intended addressee. Note the change of addressee in *Joan, Max bought me this beautiful ring for our anniversary, didn't you Max, you sweetie!* and the nonspecific addressee in

Congratulations, <u>whoever</u> came first! A 'ratified participant' can reject the H role more freely than an addressee and with less of an affront to S's face. When S is speaking, all those who can reasonably consider themselves ratified participants are expected, as part of the cooperative endeavor, to keep tabs on what is said, so that if called upon to participate they may do so appropriately.

Any other person hearing U is an overhearer: either a bystander or an eavesdropper. People in earshot are expected to overhear, though not necessarily to listen; only H's are properly expected to listen. As everyone knows, it can happen that U is overheard by someone when there was no original specific intention on S's part that this should happen; to put it more precisely, S has a reflexive-intention towards H but not towards an overhearer. An overhearer may perchance understand the message the same way that H does; but, because s/he is not necessarily party to the appropriate contextual information relevant to the correct interpretation of the utterance, it is possible that s/he may seriously misinterpret it. So, a bystander within earshot was not originally intended as a H and may, depending on circumstances, accept or reject the role of H without loss of face; consider an occasion where X is arguing with Y in earshot of Z:

[X to Y as addressee]	Shut up or I'll lay one on you.
[Y to Z as ratified participant]	You heard him threaten to hit me, didn't you?
[X to Z as bystander]	You mind your own business.
[Z to both X and Y, rejecting the role of H]	I wasn't listening.

An eavesdropper can only admit to listening in at the expense of their own positive face, because it makes her/him look bad, and sometimes also at the expense of S's negative (impositive) face, because S feels affronted by the intrusion.

5. Felicity Conditions

Austin argued for four kinds of felicity conditions: (a) a preparatory condition to establish whether or not the circumstances of the speech act and the participants in it are appropriate to its being performed successfully; (b) an executive condition to determine whether or not the speech act has been properly executed; (c) a sincerity condition—which has a similar function to Grice's (1975) maxim of quality (see *Cooperative Principle*); and (d) a fulfillment condition determined by the perlocutionary effect of the speech act. If all the relevant felicity conditions were satisfied for a given illocutinary act, Austin described it as 'happy' or 'felicitous.' One can immediately dismiss (d) as irrelevant to a linguistic theory of speech acts because it has only a contingent link with the meaning of U. The other three felicity conditions merit brief discussion here.

The statement of preparatory conditions is obligatory in definitions of illocutions. The preparatory conditions identify what ought to be presupposed in a felicitous use of the illocution. For example, the preparatory condition on an assertion such as *France is a republic* ($=p$) is 'S has reason to believe that p.' If S had said *France is not a republic*, S would be condemned for being ignorant, deluded, insane, or maliciously attempting to mislead H. It is notable that presupposition failure (in, say, *In 1990, the King of France died*) gives rise to exactly the same response. In both cases, Austin would say 'the utterance is void.' Condemnation as a response to preparatory condition failure is common to all illocutions. Take the preparatory condition on thanking: 'H, or someone or something in H's charge, has done some deed D with the apparent intention of benefiting S (directly or indirectly)'; if S thanks H for D when H never did D, H will conclude that S is either deluded or is being sarcastic. Finally, take the case of the tennis player in the US Open who claims that his opponent's ball is 'out' when the umpire disagrees: the claim has *no standing* because the player is not a person sanctioned by the preparatory conditions on this illocutionary act to declare the ball out of play. Again, by violating the preparatory conditions, S risks condemnation. The question arises whether the preparatory conditions on an illocutionary act really are its presuppositions, as Karttunen and Peters (1979: 10) apparently believe. The problem, which cannot be solved here, is that only some illocutionary acts have truth conditions, yet the standard definition of presupposition is based on truth conditions (X is a presupposition of Y if it is true that Y entails X and also true that $\neg$Y entails X). Some alternative definition of presupposition seems called for, cf. Seuren (1985, 2000), Allan (2001).

Austin requires that the procedure invoked by the illocutionary act 'must be executed by all participants correctly and completely.' He exemplifies this 'executive condition' with *I bet you the race won't be run today* said when more than one race was arranged for that day. But such misexecutions should be dealt with under generally applicable maxims of the cooperative principle. The only executive condition which still seems warranted to linguists is one on declarations which either bring about or express decisions on states of affairs such as marriage, job appointment/termination, or umpiring. Because they rely for their success on S being sanctioned by the community to perform the acts under stipulated conditions, it may be necessary to safeguard society's interest with an executive condition requiring some watchdog other than S to ensure that the sanctions are respected. These sanctions need to be written into the

preparatory conditions on the act; they identify the attitude or behavior that must be observed by S when executing the illocutionary act in order for it to be felicitous.

The sincerity condition on a speech act involves S's responsibility for what s/he is saying (asking, etc.). If S is observing the cooperative maxim of quality, then s/he will be sincere; and, normally, H will assume that S is being sincere unless s/he has good reason to believe otherwise. Generally, scholars have assumed that different kinds of illocutionary acts involve different kinds of sincerity conditions: for example, assertions and the like are sincere if S believes in the truth of the proposition asserted; requests are sincere if S believes that H can do A and might be willing to do A; declarations are sincere if S believes that s/he has the proper authority to make the declaration. Obviously, sincerity reflects on whether or not S upholds the preparatory conditions, so only one sincerity condition should be necessary: in uttering U, S knows or believes (or believes s/he knows) that all clauses of the preparatory condition hold. This puts a burden on precise statement of the preparatory conditions; but that seems exactly where it should lie, because preparatory conditions identify the particular circumstances appropriate to performing a given illocutionary act.

To sum up: the only one of Austin's original felicity conditions that remains obligatory in the definitions of all illocutions is the preparatory condition. An executive condition may be valid for declarations. Some scholars still include sincerity conditions within definitions for illocutionary acts, but sincerity can be captured by generally applicable conditions on language use. Finally, linguists rarely attend to fulfillment conditions, nor should they—though these will remain important to scholars in other disciplines concerned with perlocutionary effects of utterances. The burden of felicitous illocution will depend on proper observation of the preparatory conditions on each illocutionary act. These conditions provide the grounds for motivating S to make the utterance and grounds from which H will evaluate the illocutionary act expressed in the utterance.

6. Explicit Performative Clauses

The characteristics of explicit performative clauses are as follows. The clause must contain a verb that names the illocutionary point of the utterance, for example, *admit, advise, apologize, ask, assert, authorize, baptize, bet, charge, claim, command, congratulate, declare, order, pardon, permit, prohibit, promise, refuse, say, suggest, swear, tell, thank, urge*. It must be in the present tense; in English, it is typically in the simple aspect, but may be progressive: thus *I promise/ am promising to accompany you* are performative; *I promised/have promised to accompany you* are not.

An explicit performative clause may be negative; it may be emphatic; and it may contain the adverb *hereby*, meaning 'in/by uttering this performative' (but not meaning 'using this,' referring to something in the context). It must be 'realis' and denote the actualization of the illocutionary act; therefore *I must hereby take my leave of you* is a performative, *I might hereby authorize your release* is not. Finally, S must be agent for whoever takes responsibility for enforcing the illocutionary point of U.

7. Classes of Speech Act

There have been two approaches to classifying speech acts: one, following Austin (1962), is principally a lexical classification of so-called illocutionary verbs; the other, following Searle (1975a), is principally a classification of acts. Lexical groupings of semantically similar illocutionary verbs are made on an intuitive basis, perhaps with some reference to the syntactic environment of the verb (as in Vendler's 1972 classes), for example, expositives N_i V *that* p, such as *state, contend, insist, deny, remind, guess* versus, say, commissives N_i V *to* V, such as *promise, guarantee, refuse, decline*; exercitives 'exercising of powers, rights, or influences' (N_i V N_j *to* V), for example, *order, request, beg, dare*; or behabitives N_i V N_j P nom (past (V)), for example, *thank, congratulate, criticize*, or Ballmer and Brennenstuhl's (1981) formula *Someone VERB ((ADDRESSEE) by saying) '...'* (ABBREVIATION: nom = nominalization).

Searle (1975a) used four criteria—illocutionary point, direction of fit, S's psychological state, and propositional content—to establish five classes of speech acts. 'Representatives' have a truth value, show words-to-world fit, and express S's belief that *p*. 'Directives' are attempts to get H to do something, therefore they show world-to-words fit, and express S's wish or desire that H do A. 'Commissives' commit S to some future course of action, so they show world-to-words fit, and S expresses the intention that S do A. 'Expressives' express S's attitude to a certain state of affairs specified (if at all) in the propositional content (e.g., the underlined portion of *I apologize for stepping on your toe*). There is no direction of fit; a variety of different psychological states; and propositional content 'must ... be related to S or H' (1975a: 357ff.). 'Declarations' bring about correspondence between the propositional content and the world, thus direction of fit is both words-to-world and world-to-words. Searle recognizes no psychological state for declarations. Searle's classification has been widely adopted.

Using H's evaluations as criteria, it is possible to establish links between classes of illocution and major clause types. 'Statements' (including denials, reports, predictions, promises, and offers) are principally expressions of S's belief about the way the world was, is, or will be, and are most typically

formulated with a declarative clause. They can be judged in terms of the question 'Is *p* credible?' 'Invitationals' are a proper subset of Searle's directives, and include requests, exhortations, suggestions, warnings, etc. which principally invite H's participation. Many are formulated in an interrogative clause and prompt the question 'Does S really want A to be done, and if so is H both able and willing to do it?' 'Authoritatives' include the rest of Searle's 'directives' and his 'declarations' (commands, permissions, legal judgments, baptisms, etc.) which have S 'laying down the law.' Many of them are formulated in an imperative clause, the rest in a declarative. For these, H must consider the question 'Does S have the authority to utter U in the given context?' 'Expressives' (greetings, thanks, apologies, congratulations, etc.) have social-interactive-appropriateness values: 'Has something occurred which warrants S expressing such a reaction to it?' These principally express social interaction with H; many are idiomatic, the rest are in the default declarative clause format. All four classes of speech acts can be conveyed using a declarative clause; but interrogatives typically indicate invitationals, imperatives authoritatives, and idioms expressives.

8. Definitions of Illocutions

Definitions of illocutions are an extension of the semantics of the key verb naming the illocution, for example, *assert, deny, boast, suggest, promise, threaten, offer, command, baptize*, etc. Such a verb is just one kind of illocutionary force-indicating device or IFID. Another kind of lexical IFID is *please*: compare the information-seeking question *Are you leaving?* with the request that H leave in *Are you leaving, please?* The hyperbole in *Your bedroom's a pigsty!* implies not only condemnation but also often the command to clear it up. Idioms like *Would you mind* ... minimize an impending imposition. There are morphological IFIDs marking clause-type and politeness levels in Japanese and other oriental languages. There are syntactic IFIDs like word order and clause-type (mood), cf. *You can do A versus Can you do A?* Versus *Would that you could do A*. Last, there is prosody or punctuation; contrast *Out?* with *Out!* In most utterances, the recognition of an illocution requires reference to cooperative conditions and/or the context of utterance (see Sects. 9, 10, 11 below).

Austin cleared the ground and laid the foundations for speech act theory, and to him goes the credit for distinguishing locution, illocution, and perlocution. But it was Searle (1969: chap. 3) who first established criteria for the definitions of illocutions, using promising as his example. (a) 'Normal input and output conditions obtain.' That is, the situation of utterance (including participants) is favorable to successful communication. (b) 'S expresses the proposition that *p* in [U].' (c) 'In expressing that *p*,

S predicates a future act A of S.' Conditions (b) and (c) constitute the 'propositional content' referred to in specific definitions of illocutionary acts (in this instance, promising); scholars since Searle have usually extended this component of a definition to a description of utterance content that names the illocution, thereby including the IFID that Searle expressly omits (Vanderveken 1990 is an exception). Rules (d) and (e) identify 'preparatory conditions' on the illocution; (d) being specific to promising, and (e) being 'to the effect that the act must have a point.' Rule (e) should be enshrined within general statements of cooperative conditions on language use because it is normally relevant to all illocutionary acts and does not need to be stated within any particular definition. (f) is a sincerity condition (see Sect. 5 above). (g) 'S intends [U] will place him under an obligation to do A' is to be taken together with (h), which identifies S's reflexive-intention, 'S intends (i-1) to produce in H the knowledge (K) that [U] is to count as placing S under an obligation to do A. S intends to produce K by means of the recognition of i-1, and he intends i-1 to be recognized in virtue of (by means of) H's knowledge of the meaning of [U].' Searle calls this 'counts as' condition 'the essential rule.' Others have adopted or adapted it into an 'illocutionary intention.'

A survey of speech act definitions in Searle (1969), Bach and Harnish (1979), Edmondson (1981), Levinson (1983), Allan (1986), and Wierzbicka (1987) reveals great similarity despite the different perspectives of these scholars. The obligatory components of the definitions of illocutions are the preparatory condition and S's illocutionary intention. The propositional or utterance content will be either given or inferable from one or both of these. Finally, it was suggested in Sect. 5 that a single sincerity condition holds for all acts.

9. Being Literal or Nonliteral, Direct or Indirect, On-record or Off-record

An indirect speech act is one in which S performs one illocutionary act (e.g., stating *It's cold in here*), but intends H to infer by way of relying on their mutually shared background information, both linguistic and nonlinguistic, another illocution (e.g., requesting the heating to be turned up); cf. Searle (1975b: 61), Bach and Harnish (1979: 70). Sadock (1974) identified some exotic species of indirect acts: 'whimperatives' indirectly request (the function of the imperative in Sadock's view) by means of S directly asking a question, for example, *Can't you (please) do A?* and *Do A, will you?* (this analysis is criticized in Allan 1986: 216); using a 'queclarative,' S directly questions and indirectly makes an assertion—*Does anyone do A any more?* means 'Nobody does A any more'; 'requestions' are quiz questions to which S knows the answer, for example, *Columbus*

discovered America in? Because the clause-type determines the direct or primary illocution (Allan 2001), all speech acts are indirect; so, rather than postulating a binary distinction (direct versus indirect), it is preferable to allow for an open-ended series of illocutions ranged from the primary illocution (determined by clause-type) to the last illocution that can be inferred from a given utterance (which is the illocutionary point).

The study of indirect speech acts has overwhelmingly dealt with requests. Blum-Kulka et al. (1989: 18) identify nine points on an indirectness scale for requests. Their 'direct strategies' are used when S is dominant: (a) imperative *Clean up that mess*; (b) performative *I'm asking you to clean up that mess*; (c) hedged performatives *I would like to ask you* to come *for a check-up*; (d) obligation statements *You'll have to move that car*; (e) want statements *I want you to stop calling me*. What they call 'conventionally indirect strategies' are H-oriented: (f) suggestory formulas *How about cleaning up?*; (g) query preparatory (Sadock's 'whimperatives') *Could/Will you clear up the kitchen, please?* Finally, their 'nonconventionally indirect strategies' are off-record: (h) strong hints *You've left the kitchen in a dreadful mess*; (i) mild hints *I say, it's a bit chilly in here, isn't it?* (said when the heating is off and the window open).

The contrast between direct and indirect illocution is muddied by the related contrasts between being on-record versus off-record, and being literal or nonliteral. Blum-Kulka et al.'s 'nonconventional indirect' requests could be classified 'off-record'; the 'direct' and 'conventionally indirect' ones 'on-record' because an on-record U spells out the message explicitly. Note that S can be on-record and either direct or indirect; but if S is off-record, s/he is necessarily indirect. For someone who is not very close to S to respond to the invitation *Do you want to come to a movie tonight?* with the bald-on-record refusal *No* is downright offensive. To avoid giving offence, people hedge, apologize, prevaricate, and speak off-record, giving reasons for not accepting the invitation or complying with the request. Thus, to politely refuse the invitation, one says things like *I have to wash my hair* or *I'd love to, but my mother's coming to dinner tonight*. Note that these might be literally meant on-record statements of S's plans, but their illocutionary point is indirect and off-record refusal.

A nonliteral U such as the sarcastic *I'm sure the cat likes you pulling its tail* is an indirect, off-record request for H to desist. What makes it nonliteral is that S does not really mean it as a direct assertion about what the cat likes; in other words, it is the illocution which is nonliteral. However, there is no reason to believe that the literal meaning of *Max is a bastard* is any more direct than an utterance

intending the nonliteral meaning of 'bastard'; furthermore, both interpretations are on-record. The psycholinguistic evidence (cf. Gernsbacher 1990: 89) is that all possible senses of a language expression are activated, and context then suppresses the activation of inappropriate meanings; consequently, there is no reason to believe that the nonliteral meaning of a lexically ambiguous term takes longer to process than its literal meaning; and there are therefore no grounds at all for suggesting that it is less 'direct.' What is nonliteral in the last example is the locution, not the illocution. Take another, problematic example: *If it's not Schlitz, it's not beer*. This is a direct, on-record assertion, but it is nonliteral because S does not really mean that a can of Budweiser or Foster's is not beer, though S might literally mean that in S's opinion (but not everybody's) Budweiser and Foster's lack the properties necessary for it to be properly classified as beer. Thus, one concludes that S is indirectly asserting the opinion that Schlitz is the best beer—and literally means this; there will be different views on whether or not this opinion is on the record.

It is not enough to retain the term 'indirect illocution' only for an illocution that is either off-record or nonliteral or both. Suppose S asserts *Ted's BMW is giving him trouble*. This entails the on-record proposition that 'Ted has a BMW' and it is indirect because S does not directly assert it (pace Russell). Presumably S literally means 'Ted has a BMW' because s/he presupposes its truth (i.e., purports to do so). One concludes that illocutions which are on-record and apparently literally meant are 'indirect' if they are entailed or implicated in U; also if they are off-record, or nonliteral, or both. The so-called 'conventionally indirect' illocutions are on-record, not S-dominant but H-oriented: this solves the problem that they do not necessarily translate into other languages (see Sect.12).

10. More Than One Illocution in U

Coordinate, conjoined, and appositive clauses contribute more than one illocutionary point to U. With *I resign from the board and promise not to speak to the press*, S resigns and makes a promise. With *Welcome to the show; now, what do you do for a living?*, S welcomes H and asks a question. With *I met Celia— Did you know she was married, by the way?—at a party last night, and she told me the latest scandal at number 25*, S performs an informative interrupted by a question and conjoins to the informative a report.

One serious weakness with speech act theory has been to pretend that each U has only one illocutionary point. As Labov and Fanshel (1977: 29ff.) pointed out, 'most utterances can be seen as performing several speech acts simultaneously....

Conversation is not a chain of utterances, but rather a matrix of utterances and actions bound together by a web of understandings and reactions.... In conversation, participants use language to interpret to each other the significance of the actual and potential events that surround them and to draw the consequences for their past and future actions.' Speech acts must be interpreted with attention to their context and to their function as an integral part of social interactive behavior. Here is a common enough example:

S₁: Would you like another drink?
S₂: Yes, I would, thank you.

S_1 asks a question and concomitantly makes the offer to bring S_2 a drink, if that is what s/he wants. S_2 responds positively both to the question and to the offer, and coordinates with these illocutions a statement of thanks. Some situations allow for quite a large number of illocutionary points to be scored. Consider a public condemnation like that of the woman at a party who cries out *Mrs Trumpington, will you please ask your husband not to touch me up?!* S does several things simultaneously: (a) she makes a literal on-record request to Mrs T that she ask Mr T to stop harassing S; (b) she broadcasts on-record, literally, but indirectly, what Mr T is doing; (c) she makes a literal on-record indirect request that he stop—despite the on-record indirect expression of her belief that he will not stop of his own volition; (d) off-record, S indirectly intends not only that Mrs T condemn her husband for sexual harassment of S, but (e) that everyone in earshot should do so too.

Another weakness of speech act theory is to pretend that S's illocutionary intentions can be precisely pinned down. Suppose that one morning as H is getting ready for work, S volunteers *It's 7.45.* This informs H of the time. One may or may not be overestimating S's intention if one assumes that s/he thereby implies that it is past the time when H should have already left for work, hence warning H that s/he is running late and furthermore counseling H to hurry. U may merely have been intended to draw H's attention to the time, leaving H to draw whatever conclusion s/he wished. H might be grateful for having the matter brought to his/her attention; get angry with S for interfering; respond by hurrying; respond by suing for divorce; there are innumerable possible responses. S discovers only through H's response the perlocutionary effect of U, and thence whether his/her intentions have been realized—always assuming S has any clear idea what these are!

11. The Inferential Analysis of Speech Acts

The inferential theory of speech acts developed out of proposals originally made by Searle (1975b),

subsequently refined in the 'speech acts schema' described by Bach and Harnish (1979), and in Allan (1986: chap. 8). When S wishes to communicate with H, s/he will express him/herself in a way that s/he presumes will enable H to comprehend the intended message. The inferential theory of speech acts presents an abstract model of each step necessary in H's reasoning out of S's illocutionary point(s) in uttering U. There is an assumption that both S and H are normal human beings—that is, neither is a genius, a clairvoyant, nor a fool; both know the language L and how to use it; and they have the general knowledge that one can reasonably attribute to such persons in the particular context of utterance.

The stages in H's reasoning are taken to be as follows:

(a) Perception and recognition of U as linguistic.
(b) Recognition of U as an expression *E* of language L spoken with prosody Φ, and of the sense or senses of the locution. This is done on the bases of the cooperative principle (the term is used here to include the reasonableness condition, the communicative presumption, face concerns, and the like), and H's knowledge of lexiconic syntactic, and prosodic contributions to meaning—all of which must be specified within a general theory of meaning, though not within a theory of speech acts.
(c) Recognition of what S is denoting/referring to in the (model of the) world and time spoken of, $M^{w,t}$ (cf. Allan 2001).
(d) Recognition of the primary illocution of U on the basis of the mood of the clause in the locution, and the definitions of the five or so primary illocutionary acts which form part of the theory of speech acts.
(e) S's presumed reason for performing this primary illocution is sought in the light of various assumptions and presumptions of the cooperative principle, knowledge of L, and the use of L (including knowledge of the definitions of illocutionary acts), context, and background information of many kinds. This process may lead to a number of illocutions being inferred, ranged in a sequence from primary illocution to illocutionary point.
(f) The illocutionary point (or points) of U, that is, S's message in U, is recognized when at last no further illocutions can be inferred, and the inference schema shuts down.

An utterance such as (4) trades on the cooperative requirement that H should have a good reason not to comply with such a request:

Why don't you be quiet?

Consider the following inference schema:

In uttering (4), S intends H to reason that:	*Basis:*
1. S utters U in C. [Recognition of the utterance act]	Hearing S utter U in C.
2. $U = \Phi E$ in English, and ΦE means 'S asks why don't you be quiet?' [Recognition of the locution]	1, cooperative principle, knowledge of English.
3. By 'you,' S means 'H.'	2, theory of reference, context.
4. S is using ΦE to mean 'S asks H to give a reason not be quiet.' [Recognition of reference and denotation]	2, 3, theory of denotation, context.
5. S reflexively-intends U to be taken as asking a reason to be given for H not to be quiet. [Recognition of the primary illocutionary intention]	4, definitions of illocutionary acts.
6. S is asking for a reason to be given for H not to be quiet. [Recognition of the primary illocution]	5, definition of interrogatives.
7. S's reason for asking this is to be informed of the reason for H not to be quiet; that is, S reflexively-intends U to be taken as a reason for H to tell S H's reason not to be quiet. [Recognition of the secondary illocutionary intention]	6, cooperative principle, definitions of illocutionary acts.
8. S is questioning H as to H's reason not to be quiet. [Recognition of the secondary illocution]	7, definition of questions.
9. S's question presupposes that H has been noisy. Noise imposes on others; it seems it has imposed on S. It is impolite to impose on others, therefore the person doing it should desist or else give a reason for not being able to desist. Any other action is uncooperative, and S must know this.	8, semantic theory, ?context, cooperative principle.
10. Therefore S reflexively-intends that U be taken as a reason either for H to be quiet or to inform S of the reason for being unable to be quiet. [Recognition of the tertiary illocutionary intention]	8, 9, definitions of illocutionary acts.
11. S is requesting H either to be quiet, or to tell S the reason for being unable to be quiet. [Recognition of the tertiary illocution]	10, definition of requestives.
12. There is no reason to believe any further illocutionary intention can be inferred, therefore S is either requesting H to be quiet or questioning the reason for being unable to be quiet. [Conclusion as to the illocutionary point of U]	4,11, context, background information.

People are not expected to expressly offer reasons for being cooperative, but they are expected to offer reasons for not being cooperative: which is why there is the disjunctive illocutionary point to (4). Notice how the question illocution is carried down through the schema to become one of the disjuncts of the illocutionary point of the speech act.

Having recognized the utterance act, H must recognize S's locution. To accomplish this, H must recognize that U consists of expression E from language L spoken with prosody Φ. The first step in the process is for H to make the communicative presumption that S intends to communicate with him/her using language as a medium. This presumption is based in part on a categorizing ability to which H must have recourse at various levels in the analysis of utterance meaning. H takes the sense data from constituents of U and categorizes them using his/her linguistic knowledge, so as to perceive them in terms of a linguistic category. Perhaps the initial categorization is to recognize U as made in language L; this might be crudely described as matching H's perception of U and its parts with the languages that s/he knows. In practice, H usually has a clear expectation about which language S is using because of former experience with S or the situation of utterance; where this is not the case, there will be a heuristic interactional process along the following lines: (a) U sounds as though it is made in L_b; (b) constituent e_i of U seems to be a constituent of L_b; (c) if constituent e_j also seems to be a constituent of L_b, then e_k will be another; (d) if there is no counterevidence, then S is speaking L_b (this procedure is speculative and not experimentally confirmed). Having established that U is made in L, H must use his/her knowledge of L when categorizing what s/he perceives in U as particular lexiconic, syntactic, and prosodic constituents of L. For instance, H needs a knowledge of L's lexicon and how to use it, in order to match the appropriate set of lexicon entries with the lexicon items which s/he perceives S to use in U. H must use knowledge of the syntactic properties of lexicon items in establishing their scope relations and the syntactic structures which combine them in U. Once these are recognized, H can determine the meanings of E's

205

constituents, and the meaning of *E* itself; H will then take into account the effect of the prosody Φ on the meaning of *E* in order to determine the sense or senses of the locution ΦE.

The next step for H is to recognize what S is denoting in the (model of the) world and time spoken of, $M^{w,t}$. To do this, H will match the sense(s) of *E*'s constituents with entities in $M^{w,t}$, using knowledge of the correlation between sense and denotation/reference. Having determined the denotation/reference of U, H uses knowledge of the definitions of illocutionary acts to determine S's illocutionary intention in U. Once again, it is a matter for H's categorizing ability: this time, H perceives what S is denoting by means of the locution ΦE, and s/he must determine what kind of message S intends to communicate using this proposition. The set of illocutionary intentions is located among the definitions of illocutionary acts which constitute a part of H's linguistic knowledge (and are presumably located along with other information about meaningful properties and meaning relations). Recognition of the illocutionary intention will lead to the identification of the illocutionary act which it helps to define. There are only five primary illocutionary acts, each being determined by the form of the locution. To determine the illocutionary point of U, H invokes the reasonableness condition and seeks some reason for S's primary illocution in the context, C; the conversational maxim of relation (or relevance) will often be invoked too, and so may the other maxims of the cooperative principle—though these are more likely to be called upon at later stages. H will need to keep tabs on the meaningful properties of U and its constituents at this as in all subsequent steps leading to the decision on the illocutionary point of U; s/he must also constantly monitor the semantic relationships of U and its constituents to their textual environment; the semantic properties and relations of U may well be significant to its proper interpretation. In seeking a reason for the primary illocution, H looks to the context C, and will also check background knowledge of many kinds, including knowledge of the kinds of things that people might say in C, and the kinds of reasons that other speakers might have had when employing a similar primary illocution; in other words, H uses knowledge of L and the use of L to infer from the primary locution and the circumstances of utterance what the illocutionary point might be. This may lead through a number of indirect illocutions. The illocutionary point is only recognized when H can infer no further illocutions in U. When H recognizes the illocutionary point, s/he has finally determined the meaning of U.

Although this description offers a rational model for H's understanding of U, it is misleading because it pretends that each step is completed before the next is begun. This cannot be true because, in reality,

people interpret parts of utterances as they are presented. The inferential theory of speech acts needs to be reworked to allow for this.

12. Speech Acts and Intercultural Pragmatics

Different cultural conventions and belief systems in different language communities result in different cooperative conventions. For example, there are different linguistic politeness strategies to reflect the culturally validated perceived roles of S and H, and whatever is being spoken of. Social interactive practices such as societal attitudes to the roles of men and women vary greatly across cultures; and, as a result, so do the language conventions which people use. Acts of complimenting and thanking are more frequent, in Anglo communities than in, say, China or Africa. The Japanese and Chinese find refusing more offensive than Americans do, and so refuse off-record by using proverbs and impersonals. Preparatory conditions on illocutionary acts defined for one language cannot be expected to be universal. Intercultural miscommunication arises from the assumption that the language strategies appropriate to the delivery of the intended meaning in L_x can be used with equal efficacy in L_y. For instance, direct translation of the English *Would you like to go the cinema with me?* into Polish *Czy miałabyś ochotę pójść ze mną do kina?* will be interpreted as a direct question and not an invitation; the counterpart Polish invitation *Możebyśmy poszli do kina?* 'Perhaps we would go to the cinema?' will probably misfire in English as an intended invitation, because the off-record implication in Polish—'if I asked you?'—is lost (cf. Wierzbicka 1991: 29).

All major speech act theorists have ignored cultural diversity, leaving it to empirical studies such as the Cross-Cultural Speech Act Realization Project (CCSARP) to investigate (cf. Blum-Kulka et al. 1989) (see *Discourse in Cross-linguistic and Cross-cultural Contexts*). This project investigated and confirmed cultural differences in strategies for requesting and apologizing in German, Hebrew, Danish, Canadian French, Argentinian Spanish, British, American, and Australian English. For instance, both Americans and Israelis generally prefer to use on-record H-oriented requests rather than off-record ones, but the second preferences differ: Hebrews prefer S-dominant direct requests, whereas Americans favor the off-record strategy. Interacting with familiars but not intimates, Slavs, Hebrews, and Germans use direct on-record requests mitigated with, for example, modal particles and diminutives (cf. Wierzbicka 1991); English lacks such devices and therefore uses fewer S-dominant strategies. There is much ongoing research into illocutions which touch on politeness concerns, because it is so very important to avoid inadvertently causing offense in social interaction, especially when H is from

another culture. (See *Politeness*; *Ethnography of Speaking*.)

13. Speech Acts and Discourse

Speech act theories have treated illocutionary acts as the product of single utterances based on a single sentence, thus becoming a pragmatic extension to sentence grammars. In real life, people do not use isolated utterances: U functions as part of a larger intention or plan. Attempts to break out of the sentence-grammar mold were made by Labov and Fanshel (1977) and Edmondson (1981), and then increasingly by researchers into cross-cultural spoken discourse (see Blum-Kulka et al. 1989). The field of artificial intelligence has taken up speech acts in the context of modeling S's plans and intentions when uttering U (see Cohen et al. 1990). Consider the following interchange in a pharmacy:

Customer:	Do you have any Actifed? [Implies the intention to buy on condition Actifed are available, seeks to establish preparatory condition or transaction]
Clerk:	Tablets or linctus? [Offers a choice of product, establishes preparatory condition for transaction]
Customer:	Packet of tablets, please. [Requests one of products offered, initiates transaction. Notice that in this context, even without the IFID 'please,' the noun phrase alone will function as a requestive]
Clerk:	That'll be $10. [Directly states the payment required to execute the transaction; thereby indirectly requesting payments to execute it]
Customer proffers money:	OK. [Agrees to contract of sale and fulfills buyer's side of the bargain]
Clerk accepts money, hands over goods:	Have a nice day. [Fulfills seller's side of the bargain and concludes interaction with a conventional farewell]

As in most interactions, the interlocutors each have an agenda; and to carry out the plan, the illocutions within a discourse are ordered with respect to one another. The effect is to create coherent discourse in which S upholds his/her obligations to H. Future work on speech acts needs to account for the contribution of individual speech acts to a discourse or text; and that leads into the realm of conversational or discourse analysis (see *Discourse*; *Conversation Analysis*).

Very little work has been done on the contribution of the illocutions within utterances/sentences to the development of understanding in written texts. Texts, whether spoken or written, display one or more of four perlocutionary functions, according to Brewer and Lichtenstein (1982). Social interaction predominates in what Malinowski (see *Malinowski, Bronislaw Kaspar*) called phatic communion (social chit-chat), informativeness predominates in academic texts, persuasiveness in election speeches, and entertainment in novels. But many texts combine some or all of these functions in varying degrees to achieve their communicative purpose; for instance, although an academic text is primarily informative, it also tries to persuade readers to reach a certain point of view; it needs to be entertaining enough to keep the reader's attention; and most academic texts try to get the reader on their side through social interactive techniques such as use of authorial 'we' to include the reader. The contribution of the illocutions of individual utterances to the understanding of topics and episodes (macrostrucures) within texts is sorely in need of study.

Language Variation: Style, Situation, Function

Advertising

M. L. Geis

The language of advertising is language that is used in efforts to persuade or otherwise entice people to purchase products or services, vote for particular political candidates, modify their behavior (*Just say 'No'!*), or come to adopt a favorable view of some corporate entity (*We're working to keep your trust*). In the case of commercial advertising, by far the most common type of advertising, an advertisement will normally offer some product or service that is represented as satisfying some consumer need or desire—a tablet which is represented as relieving pain or alleviating the symptoms of a cold, a frozen food that is represented as being easy to prepare, nutritious, and tasty, or a brand of beer that is said to be *less filling* or to *taste great*.

1. The Advertising Register

Much of the language that occurs in commercial advertising is characteristic of what might be called the 'advertising register' (see *Register*), in which certain types of expressions are frequently used, such as elliptical comparatives (25 percent *less tar* (than what?)), complex comparatives (*More car for less money*), imperatives used to make suggestions such as *Try it, you'll like it*, rhetorical questions (*My friends, what is hamburger? Chopped ham?*), adjectivalizations (*meaty taste*), and the use of count nouns as mass nouns (*more car*). As a result, much if not most advertising language is readily identifiable as such by consumers.

Though the language of advertising contains the elements of the language of ordinary life, it is not infrequently used differently from how ordinary speakers use it. For example, in conversational uses of English, an assertion like *I'll wait for up to an hour* would normally be made, not to make a promise to wait, but to set limits on an antecedently made promise to wait, and is therefore more like a warning than a promise. Significantly, though *I'll wait for up to an hour* is logically consistent with the speaker's

waiting for less than an hour, when a speaker says this the speaker implies that he or she will wait at least an hour, for were the speaker actually to plan to wait less than an hour, Grice's Maxims of Quantity (see Sect. 3.1 below) would force him or her to say so. In contrast, when advertisers say that a nasal spray *lasts and lasts up to 12 continuous hours*, they are typically using the *up to*-construction not to restrict an antecedently made promise of 12 hours relief but to make the central promise of the commercial. However, consumers can be expected to interpret this *up to*-claim much as they do conversational occurrences of *up to*-claims and draw the inference that they will get twelve hours of relief.

Advertisers often qualify claims with the verb *help*, as in *Such-and-such helps form a seal between your dentures and gums . . . helps keep food out, dentures in*. Such an advertiser does not mean to imply that a seal will be created or that food will be kept out or that dentures will be kept in as a result of using the product. However, when an ordinary person says, *I'll help you mow your lawn* he means to imply that he will stay with the task till the lawn is mown. And, advertisers very rarely seem to make truthful *More for less claims*, e.g., *More car for less money*. A major American automobile manufacturer (cf. Geis 1982) has, for instance, three times offered more car for less money to consumers, but the comparison class that made *more car* true was in each case different from the comparison class that made *less money* true. Normally, in the case of a comparative claim, one holds the comparison class constant throughout a claim.

2. Language in Media

The role of language in advertising depends significantly on the advertising medium. In radio advertising, all that can be presented is oral language, music, and sound effects, and the efficacy of the advertisement will therefore depend heavily on what is said. In

print advertising, both verbal and graphic information is presented, and the language that is used can play a variety of roles ranging from that of attracting attention, to illustrating graphic images, to presenting information. Television advertising combines all three elements—music and sound effects, spoken and written language, and visual images—and shares with radio advertising the fact that it occurs in 'real time.' Though television is usually perceived as a visual medium, the fact is that what is said in a television commercial is often as important, if not more important than what is shown. Exceptions would be for products about which little of real substance can be said—advertisements for beer, soft drinks, perfumes, etc.

Because it is both a visual and verbal medium and occurs in 'real time,' television advertising imposes great perceptual and cognitive demands on viewers and sometimes exploits their limited perceptual capabilities by presenting conflicting written and oral language, e.g., a strong, short, and easily comprehended written claim (*Lasts 12 hours per dose*) competing with a hedged and more difficult to comprehend oral claim (*Such-and-such lasts up to 12 hours per dose*), or by presenting essentially unreadable small-print written disclaimers qualifying the oral text at the same time that the oral text is presented. Both techniques exploit the fact that people cannot simultaneously process oral and written language which is different in substance.

3. The Exploitation of Normal Modes of Consumer Reasoning

Human beings are 'inferencing' creatures, trained to 'read into' what is said as much as is consistent with the literal meaning of what is said and the context in which it is said. Thus, if a parent says *I'll give you five dollars if you'll mow the lawn* to a child, the parent expects the child to draw the inference that the parent will not give the child five dollars if the child does not mow the lawn—an invalid, but nevertheless quite compelling inference. Advertisers routinely exploit our tendency to draw such inferences.

3.1 The Cooperative Principle

Paul Grice observed that people normally conduct themselves in conversation in accord with what he called the 'Cooperative Principle,' (see *Cooperative Principle*) according to which participants in conversation are enjoined to make their contributions such that they further the purposes of the conversation by saying only things they believe to be true and have some evidence for (Quality Maxims), by saying as much as is required, but not more (Strength Maxims), by saying only relevant things (Relation Maxim), and by being orderly, brief, nonobscure, and the like (Manner Maxims). Advertisers routinely

exploit these maxims by way of encouraging us to draw inferences they are unable to defend.

When an advertiser says that his product does not contain some particular ingredient, he implies that this ingredient has undesirable properties (otherwise the claim would not be relevant) and, further, that the product itself does not have these properties as a result of containing some other ingredient (otherwise the advertiser will not have said as much about this product as is relevant and is required). Thus, when the advertiser of a cold remedy says that a competing product *Contains aspirin. Can upset your stomach*, but says of their own remedy that it *does not contain aspirin*, they imply that their remedy will not upset consumers' stomachs, an inference that the advertiser very possibly cannot defend. Indeed, this product may contain some other chemical compound that is capable of causing stomach upset in some persons. The attractiveness of implying something rather than asserting it overtly derives from the fact that one does not have to defend unasserted claims and consumers seem not to defend well against them.

3.2 Generic Claims in Advertising

Advertisers also routinely exploit normal modes of interpreting generic claims. Generic claims like *Dogs have four legs, A body in motion tends to stay in motion*, or *Force equals mass times acceleration* are normally interpreted as being very strong, even if not always universally true, claims, for they are used to attribute intrinsic properties to things, make law-like statements, and give definitions. Indeed, it was once common for linguists and philosophers to paraphrase an assertion like *Carrots are good for you* as *If something is a carrot, it is good for you* or even *All carrots are good for you*, very strong claims indeed.

Claims like *Such-and-such removes impurities from the air* or *Such-and-such gives temporary relief for hours from hemorrhoidal flareups* abound in advertising. Construed as a simple assertion, *Such-and-such removes impurities from the air* must be said to be true if the product removes as little as 40 or 20 or 10 or even 5 percent or less of the impurities in the air. Thus, surprisingly, the generic claim turns out to be quite weak.

However, an advertisement can be seen as a type of offer (a kind of Speech Act) (see *Speech Act Theory: An Overview*) in which some product or service is offered to satisfy some consumer need. Importantly, offers are subject to a sincerity condition according to which the speaker must believe and have evidence that what is being offered will satisfy the need that gives rise to the offer. In the example at hand, the need in question is for some sort of reasonable air quality, and it can be said that the offer in question is a sincere one only if the product removes sufficient impurities from the air to afford a health benefit. It is because consumers necessarily hear generic claims

like this as constituents of offers when they occur within advertisements, not simply as assertions intended only to convey information (as might be the case were they to occur in a scientific report), that they are construed as being strong claims.

4. Conclusion

Consumers can be expected to interpret the language of advertising as they do the language of ordinary life. As a consequence, when advertisers use language in some nonnormal fashion or fail to use it in accord with the Cooperative Principle, or fail to make offers that are sincere, they are able to exploit normal modes of language comprehension without actually saying things that are false. The result is deception and a deception consumers are not in a position to defend against.

Blessings

B. G. Szuchewycz

Blessings are utterances associated primarily with the sphere of religious activity, but they also appear with varying frequency in the politeness formulas and parenthetical expressions of everyday conversation. In both contexts the dominant linguistic feature is the use of formal and/or formulaic language. Blessings, particularly in religious ritual, may also be accompanied by specific nonlinguistic features including gestures (e.g., laying on of hands, the sign of the cross) and the use of special objects (e.g., a crucifix) or substances (e.g., water, oil). Concern with such patterned relationships between linguistic form, on the one hand, and social context and function, on the other, is central to the study of the role of language in social life.

Linguistically, blessings (and their opposite, curses) are marked by the use of a special language which may be either a highly formal or archaic variety of the dominant language (e.g., Classical Arabic) or a different code entirely (e.g., Latin). In addition to their specific content, linguistic features such as repetition, special form (e.g., parallel couplets), special prosody (e.g., chant), and fixity of pattern distinguish blessings from other types of speech and contribute to their formal and formulaic character.

The concept of blessing in Jewish, Christian, and Muslim thought, as in many other traditions, is concerned with the bestowal of divine favor or benediction through the utterance of prescribed words. As such, blessings represent an example of the belief in the magical power of words, other manifestations of which include the use of spells, incantations, and curses.

As an aspect of religious behavior, blessings are associated with essential components of public and private ritual activity. They are performed by religious specialists in situations of communal worship as, for example, in rituals where a general blessing of those present marks the end of the event. Blessings are also used by nonspecialists to solemnize, sacralize, and/or mark the boundaries of social events. In traditional Judaism, for example, *brokhe* 'blessings' include short formulaic expressions used in a wide variety of situations as well as longer texts associated with domestic ceremonies (e.g., a grace after a meal) and specific occasions or rites (e.g., Passover, weddings, funerals). Common to all is a fixity of form and the strict association of specific texts to specific occasions.

In the Bible, the Hebrew root *brk* 'blessing' is associated with a number of meanings. A blessing may be an expression of praise or adoration of God, a divine bestowal of spiritual, material, or social prosperity, or an act of consecration which renders objects holy. The Greek *eulogia* of the New Testament stresses the spiritual benefits which are obtainable through Christ, the gospels, and the institution of the church (e.g., liturgical blessings). Each instance—praise, benediction, and consecration—represents a social and religious act accomplished through the use of a highly conventionalized form of language.

Blessings often function as 'performatives' (see *Speech Act Theory: Overview*). A performative is a speech act which when uttered alters some state of affairs in the world. Under the appropriate conditions, if a minister states, 'I pronounce you man and

211

wife,' then a marriage has been socially established. If someone says, 'I promise,' then a promise has been made. Similarly, blessings function as religious performatives, in that the utterance of the requisite expression precipitates a change in spiritual state.

Mastery of the linguistic formulas, however, is not sufficient for the successful realization of blessings (and other performatives). The existence of an extra-linguistic institution (e.g., family, descent group, religious institution, etc.) with differentiated social roles and statuses for the blessor and blessee(s) is a necessary precondition to an authentic and valid performance of the act. Only certain individuals may pronounce a couple man and wife and create a legally binding marriage. The same is true of blessings.

Catholicism, for example, distinguishes those blessings exchanged between lay persons, the spiritual value of which depends on the personal sanctity of the blessor, from liturgical blessings, which carry the force of the ecclesiastical institution. As the institution itself is hierarchically organized, so too is the right to confer particular blessings. Some may be performed by the pontiff alone, some only by a bishop, others by a parish priest, and yet others by a member of a religious order. Similarly, and in a very different ethnographic context, among the Merina of Madagascar the *tsodrano* is a ritual blessing in which seniors act as intermediaries between ancestors and those being blessed, their juniors. A father bestows fertility and wealth on his son through a ceremonial public blessing which transfers to the son the power of the ancestors in a ritual stressing the continuity and reproduction of the descent group.

Like other performatives, blessings operate properly only within a context of social and cultural norms and institutions, which are necessary for their realization and to legitimate and maintain their force.

Much of human face-to-face interaction is ritualistic in nature, and it has been argued that the use of formalized and prepatterned linguistic and non-linguistic behavior in everyday life is evidence of a link between interpersonal rituals of politeness on the one hand, and ritual behavior in the sacred sphere on the other (Brown and Levinson 1987). Blessings are an example of a specific linguistic routine common to both.

In nonreligious contexts, blessings are evident in the politeness formulas and parenthetical expressions of everyday conversation: for example, the English 'Bless you!' as a conventional response to a sneeze. Similarly, in greetings, thanks, and leave-takings, blessings are exchanged between interlocutors and, although they may literally express a wish for supernatural benefits, their primary communicative function is as highly conventionalized markers of social and/or interactional status. In both their religious and secular uses, blessings thus function as expressions of solidarity, approval, and good will.

When embedded parenthetically within larger sentences or longer texts, blessings may also function as semantically and interactionally significant units. In oral narratives the use of a blessing (or curse) serves to communicate directly the emotional state or attitude of the speaker towards the topic, providing a means of internal evaluation and signaling speaker involvement in the text. Yiddish speakers, for example, make extensive use of a large set of fixed expressions, many of which are blessings, for just such a purpose (Matisoff 1979).

Business Language

G. Rasmussen

'Business language' is a commonly used expression but it is not always clear what is meant by it. This article deals first with what is captured by the category 'business language.' Why divide language into such subcategories as 'technical,' 'political,' 'legal,' or 'business' language? In other words, why talk about 'business language' rather than just the notion of language? Second, the article examines business language in terms of language use, comparing it with other kinds of language use.

1. The Category 'Business Language'

Business language is one of several categories of language in use. This subcategorization of language addresses the 'contextual sensitivity' of language use; that is, business language is not a language *sui generis*

with exclusive morphosyntactical structures. Business language is language used for the specific purpose of doing business; it involves the actions (including speech acts) that are undertaken for that purpose. Business actions are social actions, designed for recipients who interpret and respond to them as such. Business language is thus language used for the specific purpose of carrying out business interactions.

The notion of 'contextual sensitivity' has radical consequences for defining a certain kind of language used as business language. The fact that language users are business people is not sufficient for categorizing the way they use language as business language. Business people have other societal roles: they may be friends, tennis partners, politicians, fathers, mothers, and so forth. These roles do not influence every action they undertake; that is, these identities do not automatically have an influence on any given occasion. To say that the same language users use language for business purposes in contrast to, for instance, political purposes, is to say that they embrace the contextual feature 'business' in the language used. In other words, they make the business context relevant, by creating and affirming it through the linguistic choices they make and by the actions they undertake. In this way they orient themselves towards their roles as business practitioners.

1.1 Language in Business Interactions versus Business Language

Not all actions in business interactions are related to the business setting. Sometimes, for instance, participants in face-to-face business interactions engage in small-talk or make conversations in which the work setting has no consequence for the way they produce their actions and for the way they use language. But, some actions (for instance negotiations over the price of a product) are related to the business setting and it is through these actions that the participants realize that setting. Moreover, a specific business setting is realized (and constructed) through these very actions, and these may refer to particular business settings and the institutions or areas they represent such as, for example, marketing or production. Business language and business actions are thus produced interactively in response to situational constraints, at work in the wider context: the identities of the participants (business people), the section of the institution they represent (marketing or production), and those aspects of the local context, namely the activity that they are about to construct, such as the negotiation of a price. In sum, business language is constituted of actions in which the business setting acts both as a resource and as a framework for interpreting these actions in different ways.

2. What Constitutes Institutional Interactions as Opposed to Ordinary Interactions?

Business language is used in an institutional setting (see *Institutional Language*). The notion of business and institutional interaction invokes at least an implicit comparative dimension. Institutional interactions are task related, bearing in mind the shifts between task-related talk and small-talk in face-to-face-interactions, which are mentioned above. The participants show their orientation to these tasks by the way they conduct their interaction and, more so, by the goals they pursue. The goals differ according to institutional contexts: in a medical setting it may be a diagnosis, in a business setting the selling and buying of a product.

The institutional setting imposes constraints on the contributions the participants make, as it invokes expectations about how they are supposed to act. A news interview, courtroom proceedings, or a face-to-face business negotiation are heard as different from, for instance, conversational talk, because of the ways the participants are expected to act in these settings.

Institutional settings can even have an influence on how inferences are made by the participants. Doctors orient themselves to the institutional character of their medical interactions with patients by withholding expressions of surprise. In turn, a particular patient responds to that same institutional context by not interpreting the doctor's apparent reticence as disaffiliative, something which the patient might well have done in a conversational context (Drew and Heritage 1992).

2.1 What Constitutes Business Interactions as Opposed to Other Institutional Interactions?

Institutional interactions may be subcategorized into formal and non-formal, or less formal, settings. With regard to face-to-face interactions, courtroom proceedings impose many more constraints on the contributions of participants than other kinds of setting. The participants orient themselves to that context by exercising very few choices in terms of lexical choice, 'turn-design' (how to formulate a question), 'sequential organization' (question–answer formulae), and overall structural organization (different phases in courtroom proceedings). By these means, the participants confirm and construct the highly formal character of courtroom settings.

In comparison, business interactants make use of more choices, with the effect that the patterns of business interactions exhibit less uniformity. Face-to-face business interactions are task related but, the turn-taking procedures (Sacks et al. 1974) come close to normal conversational modes (Drew and Heritage 1992). Even business writing, which is widely considered to be formal (as opposed to literary writing and face-to-face business interactions), is

213

less formal than legal indictments and sentencing documents.

Nevertheless, interactants talk and act in a way by which they are heard to do *business* interactions as business people. In order to be heard as—and categorized and analyzed as—business interactions done by business people, activities that they engage in—such as advertising, buying and selling, making telephone calls, and attending business lunches— must necessarily have features that differ from other activities, and that differ from these same activities as they are performed by laypeople. What could these features be?

So far, research has shown that lexical choice is very important, but so too are ways of organizing negotiations by telex, fax, and telephone (Firth 1991) and ways of producing written texts (Pogner 1995). These can be related to the participants' identities as business people. Furthermore, instances of ways of organizing international and intercultural interactions have been related to the business setting in which these interactions were created. Concerning the international arena, business people can show that they represent an international institution and that the international status actually guarantees the reliability of the company they represent. In inter-cultural settings, business people cope with cultural differences by normalizing these in order to realize their tasks and goals (Firth 1996, Rasmussen 1996).

Code, Sociolinguistic

U. Ammon

'Code' in the sense with which this article deals is often specified as 'linguistic'; it seems, however, more adequate to specify it as 'sociolinguistic.' Otherwise it can be easily confused with other meanings of the highly ambiguous term 'code' which are quite different. Even with this specification it could be mistaken for the concept to which the term 'code-switching' relates, which is also often, or even mostly, used in a sociolinguistic context (see *Code-switching: Overview*). In the term 'code-switching' 'code' means nothing else than 'variety (or dialect) of a language.' Code-switching then is the switching from one variety to another, either of the same language or of different languages, in speech or writing.

This article does not deal with 'code' in this sense of variety of a language, but exclusively in the other sociolinguistic sense which this term takes on when it relates to the so-called 'restricted' or 'elaborated codes.' More specifically, it deals with the following aspects: (a) the definition of the term 'sociolinguistic code'; (b) the social conditions which generate restricted or elaborated codes (see *Socialization*); (c) some empirical evidence for restricted or elabo-rated codes; (d) the educational implications of the sociolinguistic codes (see *Education and Lan-guage: Overview*); and (e) some misinterpretations of the code theory and the critique based on these misinterpretations.

1. Definition of the Term 'Sociolinguistic Code'

The terms 'restricted' and 'elaborated code,' of which the term 'sociolinguistic code' is a hypernym, have only gradually taken on their meaning, as a result of Basil Bernstein, the inventor of the terms, and other researchers developing the theory for which they are constitutive (cf. the collections of articles which mirror this history in Bernstein 1971, 1973, and Bernstein's own presentation of the history of his theory in Bernstein 1987; see *Bernstein, Basil*). The original terms were 'public language' (restricted code) and 'formal language' (elaborated code). Rather than speaking of different languages, it would have been adequate to speak of modes of 'language use' (or styles of speech or writing). This terminology might also have caused less misunderstanding than did the term 'code.' A restricted and an elaborated code are, according to more recent conceptions, an implicit versus an explicit mode of language use. Following this line of thought, a restricted code is readily understandable only to members of the same social

214

group or network to which the speaker him/herself belongs (see *Sociology of Language*; *Social Networks*), while an elaborated code is also readily understandable to nonmembers of the group.

These abstract concepts (theoretical constructs) have been operationalized for empirical research by means of a number of indicators which have not always been specified clearly enough. Some of the indicators of a restricted code are, for instance, the use of pronouns instead of nouns for initial reference; a language use which presupposes that the hearer (reader) has already identified the referent; or by recurrent 'sympathetic circularity'—e.g., tag questions like 'isn't it?' or comments like 'you know'—by which the speaker attempts to confirm the common basis of knowledge and values on which one can usually count in in-group communication. Other indicators suggested for a restricted code were, for instance, a smaller variety of adjectives and verbs, fewer subordinated clauses or less use of the personal pronoun 'I' than in the case of an elaborated code. It seems quite clear that these are indicators of two different, though closely related, aspects of sociolinguistic codes, namely the utterance's implicitness or explicitness and the speaker's heteronomy/autonomy vis-à-vis his/her social group or network.

It also seems plausible enough that restricted and elaborated codes need not only be conceived of as binary (classificatory) concepts but, for more refined purposes, rather as a continuum of more or less restrictedness or elaboratedness, which poses the task of constructing scales for their measurement.

Furthermore, it seems important to make a distinction between an individual's implicitness of verbalization only in particular situations and his/her implicitness of verbalization in all situations. Only in the latter case is the individual's mode of language use a restricted code which, therefore, should be specified as the general habit of implicit language use, or even the inability (or incompetence) of explicit verbalization. An elaborated code is, in contrast, not limited to implicit language use but comprises both possibilities—implicit as well as explicit verbalization.

Finally, it should be stressed that these concepts are of necessity relative to the experience and modes of language use in different societies. It seems, therefore, hardly possible to give a detailed universal definition of restricted or elaborated codes.

2. The Social Conditions Which Generate Restricted or Elaborated Codes

Restricted codes tend to develop in social networks (see *Social Networks*) which are closed, i.e., members have but few outside connections, and multiplex, i.e., pairs of members share several social relationships (e.g., A is B's brother, and A and B are members of the same club, go regularly to the same pub, and the like) (cf. Fasold 1990). In such networks or social groups there is, as a rule, a broad basis of common understanding (experience and values) which does not require explicit verbalization in most situations.

Networks of that type are to be found more frequently in the working class than in the middle class, or, more generally speaking, more frequently in the lower than the higher social classes, at least within industrialized capitalist societies (see *Social Class*; *Class and Language*). The reason is that members of lower social classes are, for want of other resources, more dependent on mutual assistance in everyday life, which also explains why solidarity usually ranks high as a value among them.

Among workers and other lower-class professions there is also less need for explicit verbalization at the workplace, particularly if work is mainly manual and involves few social contacts beyond immediate colleagues (see Ammon 1977: 45–74). Therefore, as a rule, no stimuli for a change of verbal habits can be expected from contacts outside the private networks.

There is also a preference in the working class for a more status-oriented instead of a person-oriented family structure, or of a more imperative instead of an argumentative mode of child-rearing. Status orientation in a family means that roles and tasks are primarily dependent on the individual's position as, for instance, being the father, mother, oldest brother and so forth, and hardly adjustable according to personal preferences or momentary circumstances. This aspect of family structure can be understood to come about or to be stabilized as a consequence of a feedback relation with a restricted code. It provides fewer opportunities for explicit verbalization, i.e., tends to generate or stabilize a restricted code on the one hand, and the restricted code, i.e., the preference for implicit rather than explicit verbalization, makes this family structure less liable to questioning and change on the other hand. Similarly, the imperative mode of child-rearing can be explained in the form of a feedback in relation to a restricted code.

To avoid misunderstanding, it should be pointed out that these traits of social structure should again not be conceived of as binary concepts but rather as rank or interval scales (more or less closed or multiplex social networks, status-oriented family structure, and imperative mode of child-rearing), nor do they necessarily exist in the entire working class or are totally absent in other social classes. They are only statistical, not categorical differences between the social classes. Nevertheless these statistical differences amount to the fact that restricted codes are more common among the working class than among the middle class.

215

3. Some Empirical Evidence for Restricted and for Elaborated Codes

The study by Schatzman and Strauss (1955), which stimulated Bernstein's conception of the theory and which still seems valid, deserves mention here. The authors interviewed lower- and middle-class witnesses of a tornado in Arkansas. The lower-class witnesses set the scene in a way which was only partially understandable to strangers, since they referred to their personal background and to views of friends whom the interviewers could not know, while middle-class informants constructed events in a generally understandable way which did not presuppose common contextual information. Bernstein himself found discrepancies in lower-class students between verbal and so-called nonverbal IQs, which could not be confirmed for middle-class students. Verbal IQs were considerably lower than nonverbal IQs, which seems to indicate that in lower-class families verbal skills are not trained to the same degree as they are in middle-class families. There is, of course, also the possibility of social class biases of verbal IQ tests. Bernstein also found longer and more frequent pausing in utterances of middle-class students than of lower-class students, which he explained as an effect of more careful verbal planning.

Numerous studies have been done in different countries, mainly in Western Europe and North America, with findings like the following. In comparison to middle-class informants, the utterances of lower-class informants showed a smaller diversity of content words (nouns, verbs, adjectives), fewer subordinated or embedded clauses, particularly multiple embedded clauses, less use of the personal pronoun 'I,' and more sympathetic circularity. It has also been found that the utterances of lower-class informants tend to be fewer and shorter on the whole. The validity of the latter findings has been questioned on grounds of the formality of the test situation which is less familiar to lower-class informants and, therefore, has more of an inhibiting effect on them. One could, however, take this objection as a supportive argument for the code theory. It concedes the lower-class informants' increased difficulty in handling unfamiliar situations, which can be explained as a consequence of their closed social networks and restricted codes.

4. Educational Implications of the Sociolinguistic Codes

The restricted codes have been seen as a major cause, among others, of school failure of lower-class students. The negative effects of a restricted code have been assumed to occur on various levels of school requirements, though valid and reliable empirical corroborations of these assumptions are still missing.

It seems plausible that teachers value explicit verbalization in class, orally as well as in writing, which is comprehensible not only to the 'in group' but also to persons with different experiences and values. School is even, as a rule, supposed to provide students with such verbal skills, since they are part of a general qualification for many professions, particularly middle-class professions, which require the performance of public speeches or the production of generally understandable written texts. Students who already possess these skills to some degree when they enter school, i.e., middle-class students, have some advantage over those who do not, i.e., lower-class students.

The school difficulties of students with a restricted code may be aggravated by the fact that the teacher is not fully aware of their problems and, therefore, does not try to offer adequate remedy; which, as will be seen, would be hard to provide anyway. The teacher may even interpret the students' more implicit verbal behavior as a general lack of intelligence. Such a misjudgment may have far-reaching consequences. It may misguide a teacher's evaluation, his kind of encouragement, or other aspects of behavior towards the student.

There is also the possibility that restricted and elaborated codes affect apparent intelligence or learning motivation more deeply. Someone with a more implicit language use may run into fewer intellectual challenges than someone with a more explicit language use. It is an everyday experience that, only when one tries explicitly to formulate a problem, does one notice that one does not have a full grasp of it and, as a consequence, is sometimes stimulated to achieve a better understanding. It might well be true that this mechanism functions more often in middle-class families or in individuals with an elaborated code, than in lower-class families or in individuals with a restricted code, and that its effects may add up to substantial differences in learning motivation and knowledge or apparent intelligence. It seems hardly necessary to stress that these effects are not related to innate intelligence.

It has also been argued, to some degree by Bernstein himself, that a restricted and an elaborated code might enhance different views of the world, in a similar way as has been assumed for different languages by Wilhelm von Humboldt, Edward Sapir, or Benjamin L. Whorf (see *Sapir–Whorf Hypothesis*). This assumption has, however, been refuted for good reasons by pointing out that codes do not actually differ with respect to semantics, or even vocabulary or syntactic structure, but are only different ways of using the same linguistic system.

The most important educational endeavors that have been stimulated by the code theory, though not

exclusively by it, are the various attempts at so-called 'compensatory education.' Since such attempts have, as a rule, been based on more comprehensive assumptions of verbal or intellectual deprivation, their designs have also been more comprehensive than just the training of explicit language use. The children's verbal 'deprivation' in such educational contexts has often rather been seen in regional or social dialects (e.g., Black English in the USA) than in restricted codes, or both concepts have not been carefully kept apart (see *Dialect and Dialectology*). Restricted codes and social or regional dialects (or varieties) are, as pointed out in Sect. 1 quite different and should not be confused conceptually and in theory. It is, however, true that they often co-occur in social reality and that both of them can cause school difficulties, though for quite different reasons.

Theoretical shortcomings of this kind are certainly among the reasons why compensatory education has, on the whole, not lived up to the expectations it has raised. For most of the children who received it, lasting educational success could not be achieved. There are some reasons for these shortcomings which relate to the nature of the sociolinguistic codes. Perhaps the most important of them is that the codes are, as may be assumed, an integrated component of an individual's personal identity. To speak generally implicitly, or to speak explicitly in certain situations is by no means a superficial habit which can be changed rather easily by training. It is rather a deep-seated character trait which is socially highly significant and therefore crucial in educational contexts. Children who change from an implicit to an explicit mode of language use may be estranged from their social surroundings and even from their parents. Even if such a language behavior is limited to some formal situations like school and is not applied in other social contexts, its acquisition puts a lot of psychological strain on the child, apart from the fact that it is hard to retain as a skill if it cannot be applied in everyday life. These and other difficulties, which have caused compensatory education to fail in many cases are, however, no proof that successful compensatory education is generally impossible. It can yet perhaps be modeled in a way that provides educational success to many socially deprived children.

Among the numerous objections against compensatory education, of which some took issue with the whole idea while others only questioned certain of its aspects, the argument has been put forward that too much emphasis has been placed on changing the children and their habits instead of changing the school system or, for that matter, the entire society according to children's needs. This seems to be a valid general objection. If the argument was meant to imply, however, as sometimes has been the case, that—to state it baldly—the school, or even the entire society, should turn to the restricted code or simply accept it as equivalent to the elaborated code, then it seems hardly realistic. The reason is that explicit modes of verbal expression are most likely functional in numerous situations in modern societies, and in particular, in situations which occur frequently in typical middle-class professions.

5. Misinterpretations and Critique of the Code Theory

There is no question that the theory of the sociolinguistic codes, even today, does not really meet rigorous scientific standards. Besides its remaining conceptual fuzziness and theoretical shortcomings, the empirical evidence which has been presented for its support leaves much to be desired in terms of validity and reliability, as Bernstein himself would be the first to admit. There have, however, been some notorious misunderstandings, which have unjustly contributed to the theory's refutation in some quarters of the scientific community and which should be corrected.

One of these misunderstandings is the confusion of the sociolinguistic codes with dialects or varieties of a language, in spite of Bernstein's explicit warnings against this confusion. Attacks on the theory on the grounds that it would evaluate the codes as 'deficits' instead of mere 'differences' of socially determined language behavior, seem to be largely based on this confusion. The deficit objection often refers to Labov's (1970) analysis of Black English in the USA (see *Sociolinguistic Variation; Ebonics and African American Vernacular English*). This study convincingly shows that some of the features of Black English which seem to be irregular or the expression of illogical thinking, e.g., double negation—with the meaning of single negation—are in reality perfectly regular and just another way, different from Standard English, of expressing the same logical ideas. Following this sound line of thought, the deficit objection puts forth the well-known postulate, which is widely accepted among linguists, that all linguistic systems are equivalent, though of course different means of expressing human thinking. Even if this statement is accepted unchallenged (though it is, if not specified further, highly questionable in view of findings of societal language development and language modernization), it definitely misses its point, since restricted and elaborated codes are not two different linguistic systems but two different modes of use of the same linguistic system.

In the same article, Labov (1970) contrasts a lower-class and a middle-class person, finding the former's utterances succinct and logical and the latter's redundant and verbose. This evaluation has also been used extensively against the educational objective of teaching the elaborated code to lower-class students. It gives indeed reason to think about class-biased evaluations of the quality of verbal

217

utterances. Labov's findings deserve, however, to be scrutinized with respect to representativity (only single representatives of the social classes) on the one hand, and functionality of communication in various situations on the other hand. It is questionable whether the latter can be judged adequately by a single researcher on a largely intuitive basis as has been done by Labov (1970). Therefore, these and other intuitive judgments are hardly a sufficient basis for dismissing the entire code theory as ill grounded or just a reflection of class prejudices, as has been suggested.

The code theory deserves to be formulated and tested more rigorously than has been done so far. One of the central questions for empirical testing should be whether there really are differences in explicitness of verbalization between the social classes, even in situations when it is clear to the speakers that the addressees are strangers (not members of the 'in group'), and whether the spoken or written texts produced by lower-class people in such situations are really not fully comprehensible to strangers. The empirical research necessary to answer these questions goes well beyond the frame of linguistics, or even sociolinguistics, in any narrower sense, since questions of comprehensibility of verbal utterances are of major importance for them.

Context

U. M. Quasthoff

'Context' is one of those linguistic terms which is constantly used in all kinds of contexts but never explained. In a broad sense, it refers to the relevant elements of the surrounding linguistic or nonlinguistic structures in relation to an uttered expression under consideration. This expression is normally a unit corresponding to a sentence, but can also be a word or a global discourse unit.

In a more particular sense, the concept of context is widely context-dependent: it varies with the context of each particular linguistic approach, terminological system, or analytical unit. The concept also depends on the historical context: it has varied in the course of the history of linguistics in the same way that the role of context has varied in the course of the history of language(s) and ontogenetic linguistic development. What is considered to be context-independent can be proven to be highly context-bound in a different context: in archaic texts found in Mesopotamia, numbers do not represent abstract ideas of quantity, but vary in their quantification with the measured items. Thus, the same number word may mean different 'numbers' relative to what is counted (Damerow 1988).

This article will not be able to deal with all aspects of the linguistic use of the term 'context.' It will mention some, omit others, and focus on one issue which is considered to be among the most important ones for future research. The different roles and meanings of context in the context of linguistic paradigms, analytic levels, and sets of categories will be mentioned. The notion of 'context' as part of modern discourse analysis will be made explicit in some depth.

1. The Theoretical Role of Context

The central role that context plays in linguistic theorizing may be inferred from the fact that one could systematize a history of recent linguistics by describing the role of context in successive theoretical systems. In the substitution of a new paradigm for an old one, and in most of the evolutions within one and the same approach from the 1960s onwards, the global changes generally have been from a very reductive treatment of context towards models which pay more and more attention to conditions of use. (This is not to say that before 1960 there had been no place for the notion of context in linguistic theory. In

the 1940s and 1950s, 'context of situation' was a dominant feature in Firthian linguistics and, before Firth, in the work of Malinowski: see *Firth, J. R.; Malinowski, Bronislaw Kaspar.*)

Generative–transformational grammar's concept of an autonomous syntax (Chomsky 1965) as *the* 'standard' language theory was challenged first by 'generative semantics,' which moved more and more into contextual issues (e.g., Lakoff and Johnson 1980). Speech act theory (see *Speech Act Theory: An Overview*) subsequently became a popular conceptual alternative in that it considered speaking as acting under contextual conditions (Searle 1969). Furthermore, sociolinguistics defined situational and social variables in terms of 'social context.' Finally, discourse analysis (see *Discourse*) conceptualized structure in general as sequentially ordered units establishing locally and globally, forward and backward operating contextual forces (see Sect. 4 below).

Formal semantics moved from the formal representation of propositions by means of predicate logic to intentional semantics, in which the formal representations included utterance-oriented coordinates such as time and place of utterance, speaker, etc. (Lewis 1972).

As to language acquisition, conceptualizations changed from context-independent grammatical generalizations such as those of pivot grammar (Braine 1963) to the concept of 'rich interpretation' as an analytic approach to the contextual boundedness of children's utterances (Bloom 1973). Finally, early language acquisition was viewed as a process of replacing the nonverbal elements of the child's interactive situation by verbal ones (Greenfield and Smith 1976, Bruner 1974/75). The acquisition of discourse by older children has come to be seen as enabled by contextualized patterns of adult–child interaction which are specific to the child's age (Hausendorf and Quasthoff 1992).

In the course of its movement from a peripheral to a more central position in linguistic theorizing, context itself developed from a somewhat static conception in terms of one or more related utterances towards a more processual notion. Context is viewed as being built up in production as well as in comprehension of text, as changing with every new utterance, as being structured in itself. The establishment of relevant context is seen as a mutual achievement of the participants in verbal interaction, in its effect negotiable to a certain degree (see Sect. 4).

Context is dichotomized in various ways, just as it is used itself to establish other dichotomies: verbal and nonverbal elements of a relevant distribution are differentiated. The term 'context' refers solely to the linguistic environment, whereas context in this juxtaposition refers to linguistic and situational elements. A difference is made between sentence-oriented and utterance-oriented context (Wunderlich 1979), reflecting the dichotomy of language and speech, competence and performance, linguistic structure, and linguistic use. The sequential boundedness of utterances in discourse (see Sect. 4) is grasped in terms of local and global dependencies (see *Discourse*).

Context itself is used as a distinctive criterion for the differentiation of various poles in linguistic description. Spoken versus written language (see *Speech and Writing*), early stages versus late stages of language acquisition, as well as language change, everyday versus standard registers, and language varieties, are distinguished—among other aspects—by the degree of context-dependency. However, context, and consequently context-dependency, have very different readings in accordance with the unit of linguistic analysis under consideration.

2. Context in its Relation to Different Units of Linguistic Analysis

Sentence-oriented syntax acknowledges various aspects of word order as being influenced by contextual relations. The theme–rheme structure of each sentence reflects the known–new structure of the context (Sgall et al. 1973, Bátori 1981) or at least 'interpenetrates' with the given–new structure (Halliday 1985: 40). Topicalization (Sgall et al. 1973), left dislocation (Gülich 1982), left embedding (Kvam 1979), and sometimes passive voice (Quirk et al. 1978: 943) react to contextual elements in that all these factors contribute to coherence as a structural condition of transsentential units. Thus, in spite of the sentence being the unit of analysis, contextual elements have to be taken into account in syntactic description. These contextual elements can be represented in terms of the structure of neighboring sentences or the informational contours of small textual segments.

'Textual grammar' (Halliday and Hasan 1976; see *Halliday, Michael Alexander Kirkwood*) deals with various aspects of the relationship between sentences, such as coherence and cohesion, coreference, ellipsis, and even 'intertextual' relations beyond the individual texts. In other words, if text is the object of description, what is actually being described are different kinds of contextual relations.

Semantic approaches which offer structural descriptions of (elements of) propositions deal with contextually bound phenomena, or use descriptive models which rely on contextual information, or combine these two aspects. One of the most important tissues among the contextually bound phenomena is 'reference.' The semantic conditions with respect to definite or nondefinite descriptions rely on anaphorical relations as well as on world knowledge; both determine the uniqueness of referents relative to a certain text or (part of the) world, respectively. Various types of semantic inference, presuppositions, and entailments, to mention another

phenomenon, belong to the logical representation of a proposition. In view of textual chaining, however, they belong to the contextual information, to the knowledge pool associated with a prepositional expression.

Among the contextually bound descriptive formats, intensional semantics (Lewis 1972) and possible world semantics (Montague 1973) have already been mentioned. At issue here are attempts to represent possible use conditions in terms of situational determinants in the formal description of a proposition.

Procedural notions of semantics (Habel 1985b), which operationalize (sentence-)meaning as processing structures, acknowledge the context-dependency of propositional and conceptual meaning to the point where the boundary between knowledge of language and knowledge of the world becomes irrelevant. The acceptance of, for instance, defaults (that is, preliminary assumptions on the basis of world knowledge rather than cogent inferences based on logical relations), in the process of meaning attribution, shows the degree to which this approach has incorporated contextual determinants as a matter of course (Habel 1985a).

Cognitive science and artificial intelligence, as prominent representatives of this paradigm, have consequently suggested frameworks such as 'frames' (Minsky 1975), 'schemata' (Rumelhart 1977), and 'scripts' (Schank and Abelson 1977), which systematize relevant nonlinguistic knowledge elements necessary for the processing of linguistic expressions.

To summarize, in the case of semantic analysis, context can be operationalized in terms of referentially relevant elements of the utterance situation. Furthermore, 'context' can denote systems of knowledge and belief: knowledge which is logically implied but not made explicit in the proposition, or knowledge of the world which is used in terms of expectations to process sentences.

Most of what has been said in connection with propositional semantics also holds for 'lexical semantics.' On the lexical level of analysis, the focus is on the classical case of contextual influence: disambiguation of lexical items—in the cases of polysemy and homonymy—or, in terms of truth-conditional semantics, specification of the context-specific semantic value (sense) of an expression as opposed to its general 'meaning' (Pinkal 1985).

To take an example: according to Palmer, there are at least five homonyms for *mail*: 'armour,' 'post,' 'payment,' 'halfpenny,' and 'spot' (Palmer 1976: 67). Normally, the syntactic and lexical environment within a sentence already provides for the fact that in actual communication, these homonyms are almost never mixed up. Speakers and listeners in everyday situations normally do not even realize that

there are other readings to a word besides the one which they have selected.

It is a descriptive task for the truth-value approach to lexical semantics to explain the fact that, for example, the announcement made at a conference (1):

> There will be coffee in the lounge at 10:30   (1)

is not normally associated with the interpretation 'there is a bag of coffee on one of the tables in the lounge' or 'there will be some coffee powder spilled on the carpet in the lounge,' although in all these cases some variant of the lexical meaning of *coffee* is instantiated and the sentence thus would be true (Bosch 1985: 251). This task must of course be solved by models of semantic structure which combine sense and meaning in their representation.

'Pragmatic analysis' has some close connections to the semantic phenomena referred to above: while representing situational elements in the semantic description of a proposition—even if only in order to interpret deictic elements (*I, you, here, there, come, go*)—one actually crosses the border into pragmatics in the strict sense of the term. Pragmatics in this sense includes every theory with explicit reference to situational elements. Hence, Lewis's (1972) contextual indices such as time coordinate, place coordinate, speaker coordinate, and audience coordinate actually add pragmatic elements to his semantics (see *Pragmatics and Sociolinguistics*).

A more prototypical variant of pragmatic analysis, however, is speech act theory. It specifies the object of linguistic description as the act of speaking rather than as a structural system. If speaking is a special—symbolic, highly conventionalized—way of acting, then linguistic theory becomes a variant of action theory. Consequently, context comes into play in terms of felicity conditions for actions, that is, situational prerequisites which allow speech acts to be performed in the intended way: one cannot open a door which is already open. In the same way, one cannot promise something which one is expected to do anyway. Or, to quote one of Searle's (1969: 59) well-known conditions for the illocutionary act of promising: *It is not obvious to S* [speaker] *and H* [hearer] *that S will do A* [future action] *in the normal course of events* (see *Speech Act Theory: Overview*).

Situational conditions play an even more decisive role in the case of indirect speech acts (Searle 1975, Gordon and Lakoff 1975), where—roughly speaking—utterance form and illocution do not coincide. *The phone is ringing*, analyzed as an indirect speech act, would not be meant as a statement, but as a request to answer the phone. It would certainly be heard as a request instead of a statement, if the utterance situation were such that the addressee could be assumed to hear the phone him/herself. In

this case, the interpretation of the utterance as a statement would not make sense because it would violate one of the basic conversational maxims (Grice 1975), namely *Be relevant* (see *Conversational Maxims*). Since speakers do not assume these maxims to be violated, they infer via 'conversational implicature' (Grice 1975) the indirect interpretation of the illocutionary act. In other words, they use contextual information, in combination with their knowledge about general principles of communicative acting, to determine the kind of speech act in question.

In sum, from the viewpoint of speech act theory, context essentially focuses on the situational conditions for the performance and interpretation of single verbal acts. As a result, what cannot be grasped within this framework is the impact of the contextual relations formed by the rule-governed *sequences* of acts in *global structures* of *actual discourse*. This aspect is taken up by discourse analysis (see Sect. 4).

Finally, 'sociolinguistics' also clearly conceptualizes context in terms of situation (see *Sociolinguistic Variation*). Quantitative sociolinguistic studies often take into account situational factors as independent variables. Situational characteristics such as formal/informal (Labov 1972) are thus treated like other independent variables (e.g., class or ethnic group) and investigated with respect to their impact on phonological or syntactic variables. In contrast, qualitative or microanalytic sociolinguistics does not envisage the speech situation as analytically independent from verbal behavior—which would be a prerequisite for allowing correlations in a statistical sense. Rather, ethnographic and ethnomethodological conceptions (see *Field Methods, Ethnographic*; *Ethnomethodology*) visualize the definition of a situation as one of the achievements of verbal activities. In other words, situational context is not viewed as something that linguistic features have to *adjust* to; instead, a specific situational frame (Goffman 1974; see *Goffman, Erving*) is seen as *created* by means of specific verbal and nonverbal behavior in the *process* of communication.

The pragmatic insight into the action quality of speech and the microsociolinguistic conception of situational context as being achieved by communicative activities have had a strong influence on the development of discourse analysis and its concept of context (see Sect. 4). In relation to what has been said so far, however, one must generally conclude that the notions of context used on different levels of linguistic analysis are very disparate. They can refer to syntactic or semantic aspects of the immediate linguistic surrounding, or to physical elements of the utterance situation, or to mental entities like knowledge structures, or to situational conditions for the performance of acts. What is lacking is some integrated conception of the role of context in the sequentially ordered process of producing and interpreting communicative moves.

Before attempting to outline such a conception, a more precise formulation will be given of the different notions of context in relation to their corresponding theoretical frameworks, while focusing on problems that arise in connection with the various approaches.

3. Problems Associated with the Notions of Context

Aside from the surrounding deictic coordinates, aside from the immediate linguistic context and accompanying gestural expressions at closer view, the following determinants can influence the attribution of sense; the entire frame of interaction, the individual biographies of the participants, the physical environment, the social embedding, the cultural and historical background, and—in addition to all of these—facts and dates no matter how far removed in dimensions of time and space. Roughly speaking, *'context' can be the whole world in relation to an utterance act.*
(Pinkal 1985: 36; contributor's italics and translation)

On the object level, this quotation reflects the variability of context presented in Sect. 2 above. The tremendous descriptive problems which follow from the fact that 'the whole world can be context in relation to an utterance act' are evident:

  (a) some notion of *relevance* (Sperber and Wilson 1986) with reference to context has to be operationalized;
  (b) the context has to be *structured*;
  (c) *change* of context in the course of an utterance (Pinkal 1985: 36) must be handled by the descriptive format;
  (d) in addition to the speaker's perspective, the *perspective of the listener* has to be taken into account (Pinkal 1985: 37).

In other words, a satisfactory descriptive model of context must be able to answer the following questions:

  (a) How do discourse participants decide which elements of physical or verbal surroundings or of episodic or semantic knowledge systems are *relevant* for the planning or interpretation of an utterance; that is, what has become 'context'?
  (b) How do participants *organize* the relevant *contextual units*, and how do they convey this organization in interaction?
  (c) How are contextual relationships *dynamically* tied into process of the participant's mutually oriented way of producing and comprehending utterances?
  (d) In what are the contextual structures *interactively* achieved and mutually displayed by all the participants in a piece of discourse?

There is no theory of context which is able to answer all these questions with sufficient theoretical explicitness. So it is not astonishing that the concepts of

221

context discussed so far fall short in one way or the other.

Semantic notions of context are normally speaker-centered and have difficulties in accounting for the sentence-internal dynamics of context (Pinkal 1985). Text-grammatical descriptions of coherence relations mostly rely on context as being unstructured and operating only locally. They typically have a static concept of contextual relations.

Contextual notions in terms of speech act theory can be formulated as rules for the successful and sincere performance of the relevant acts. In this respect, they can be said to deal with the relevance issue: only the relevant aspects of the situational context of an action are part of the rules. With respect to the claims for an internally structured, dynamic, interactively oriented reconstruction of context, however, classical speech act theory falls short.

The processual conceptions of the information-processing paradigms are oriented towards structurally explicated knowledge systems (e.g., frames or scripts) and the dynamics of contextual conditions. They also operationalize relevance in certain small domains in order to obtain 'running' programs which generate and/or comprehend linguistic expressions. They are knowledge-based. Consequently, their model of interactivity is a cognitive one, which incorporates into the automatic system's planning not only adequate reactions to the moves of the system's partner, but also images and expectations as to his/her likely choice of procedure (Morik 1984).

The fact that artificial intelligence has developed operational solutions to the problems listed above—at least with respect to small domains of dialogic competence—certainly has to do with the fact that automatic simulation of cognitive and communicative processes is a demanding empirical field. Empirics cannot be cheated by reductionism which abstracts from essential elements of the phenomenon, whereas the kind of theory which simulates the use of utterances per introspection is often in danger of doing just that.

In order to see how discourse analysis relates to the four problems listed above, an empirically based model of the contextualized use of discourse units in conversational interaction will be examined.

4. Context and Sequentiality in Discourse

The ways in which the four descriptive problems listed in Sect. 3 were transformed into the corresponding research questions already indicate the basic orientation in the solution of these problems: an ethnomethodological insight is followed which leaves the solution of structural problems and ambiguities to the participants of the interaction. Thus, the analysis has to reconstruct how the communicative partners define, for their mutual understanding, what is relevant context.

The basic idea of the sequential model employed (Hausendorf and Quasthoff 1989, 1992) is a threefold analysis of 'jobs,' 'devices,' and 'forms' in the reconstruction of the interactive process which is constituted by the joint performance of each discourse unit in everyday conversation. Narrative data is used to develop the model; consequently storytelling is the case of discourse units, which will be presented in an exemplary way.

The descriptive level of the jobs represents the global narrative tasks to be fulfilled jointly by both participants. Consequently, this descriptive level does not yet allow the differentiation into narrator and listener activities, respectively.

Jobs are structural in nature and sequentially ordered. They are assumed to be generally applicable and thus context-free. If a narrative was successfully told, the jobs must have been done, no matter how, no matter by whom, and in no matter which situation.

The devices are formulated to be narrator- and listener-specific. They comprise the pragmatic acts of each participant. Devices are divided into local 'moves,' which organize the joint fulfillment of the global jobs, and into text-semantic elements, which constitute the global semantic coherence of the schematic structure. Devices are sequentially ordered on the basis of conditional relevances: if someone realizes move *a*, then move *b* or *c* can be expected on the basis of the predictions of the (inductively developed) model. These sequential dependencies of devices form the interactive patterns which operate in the sense of globally bound adjacency pairs (see *Conversation Analysis*). The typical interactive patterns accomplish the contextualization of the actual discourse activities. In other words, the situational frame of each storytelling in terms of what interactive game is being played (child tells mother about ... , colleagues tell stories at a party ... , instructor gives an example of...) is a matter of the particular sequences of devices.

The forms are the linguistic surface realizations of the semantic-pragmatic units provided for by the devices. Forms are sentence-bound.

Linguistic analysis in the classical lexico–syntactic sense (forms) is thus systematically bound to the pragmatic level of single linguistic acts (devices), which in turn are tied to the interactive level of the common achievement of global organization (jobs).

The role and the understanding of context in this kind of analytical model needs to be assessed (see Fig. 1). Unlike in other approaches, where a contextual relation between an utterance under consideration and its relevant surroundings has to be defined, this model gives a perspective on threads of discourse such that each utterance is viewed as a focused-on

	14-year-old narrator		14-year-old's listener

	No, I don't think so		*Was it OK to tell him?*		

Figure 1

utterance and as a context at the same time. In other words, each single unit in discourse is considered at the same time as disambiguating and defining the contextual conditions given by preceding utterances in a 'backward' orientation on the one hand, and as providing contextual offers for subsequent units to deal with in a 'forward' orientation on the other.

The basis on which participants and linguistic analysis assign structural meanings in this process of backward and forward oriented patterns of 'conditional relevances' is threefold. It contains:
(a) the rule-governed sequential implicatedness on a global and local basis which is explicated in the sequential orderings of jobs and devices in

the model and which assigns to each form a global and local structural position;

(b) the negotiation among the participants as to the assignment of particular functional roles to an utterance;

(c) the contextualization cues (Gumpez 1982) in the utterance-forms which express the discourse function associated with the utterance (Quasthoff 1992).

To take an example from narrative discourse units: the form *Paul dropped the cassette recorder* positioned in the course of the job 'display of thematic relevance' *can* be assigned the role of a story abstract. Whether it actually acquires this structural role, however, depends on the way in which the following turns treat this utterance. If the same speaker continues with *and Louise bumped her head but nothing else went wrong*, then the contextual potential of a story opening has not been used. If, however, the next speaker continues with *Oh, my God! How did that happen?* then the structural implication for a narrative discourse unit has been established and must be either obeyed or formally discharged by the subsequent moves.

The next utterance in this constructed discourse could very well be *Paul tripped over the cord*. It could also be *Paul was going to walk over there and there was this cord hanging down and he tripped over the cord*. In the case of this last utterance, the fact that Paul's action plan was disrupted by some unforeseen event is expressed in the surface of the utterance. Since the indication of a break of plans is the 'narrative function' of this 'initiating event,' it can be stated that this form offers a contextualization cue for the assignment of its structural role in the process of mutual contextualization (Quasthoff 1992).

The systematicity of the pattern produced by the participants of each actual storytelling event establishes the type of interaction which is being performed by and with these particular narrative activities. In other words, the 'situational context' is built up in the course of generating each utterance in its unambiguous functional value.

It has become possible to sketch preliminary answers to the four questions listed above in connection with the problems that will have to be solved by a satisfactory theory of context.

(a) Relevance is displayed by formal contextualization cues and finally established by the forward and backward oriented sense-making forces of each move. The establishment of these conditional relevances operates on the basis of rule-governed sequential expectations and constraints. Relevance is mutually focused structural attentiveness with respect to 'situational' and 'linguistic' sense-making procedures alike.

(b) Contextual relations are organized 'horizontally' and 'vertically' in terms of the sequential model. In other words, in a horizontal dimension, each realized form is produced and heard locally as an expression of a particular element of thematic coherence and as a particular move in the organization of interactive patterns. Globally, each form is at the same time a particular contribution to the execution of the interactive job being performed.

In the vertical, that is, sequential dimension, there are the global and the local patterns following the conditional relevances of jobs and devices. Within the framework of discourse units, the global pattern is represented by the sequence of jobs. The discourse unit is opened with 'topicalizing' and closed with 'closing.' These two jobs can thus be viewed as the contest for the discourse unit proper.

(c) The dynamic quality of the contextual relations represented by the model is indicated by the fact that the sequential implications of the interactive model can be formulated in terms of a cognitively oriented generation model (Quasthoff 1991). There, the planning procedure of linguistic forms incorporates the described influential factors on an 'on-line' basis.

But context is also viewed as a dynamic concept in that it is not represented as given by a certain utterance or situation. Rather, it is locally constructed move-by-move by the linguistic forms of each semantic–pragmatic device in fulfillment of an interactive job. This implies that context is negotiable, and that displays of relevance can be ignored, rejected, or changed to a certain degree.

(d) The interactive quality of context has already been described in connection with the rebuttal of a static notion of context. The sequential model, however, not only offers a format for the disambiguation of the implicational forces of local moves in terms of the interactive pattern. It also provides for a structural concept which represents *joint* interactive achievements as a unit in itself. The is done by the descriptive level of the jobs.

The interactive quality of discourse structures (and thus of context structures) implies a mutual disambiguation of the structural values of each move as one of the tasks of the sense-making machinery of everyday communication. Joint participation in the achievement of the same structure is only possible if the kind of structure to be achieved jointly is focused on and (made) unambiguous to the contributing participants. This is done in the

course of the activities by the activities themselves, using resources such as sequential position, content, discourse markers, and contextualization cues.

In a discourse-analytic perspective, then, context is the ensemble of locally and globally operating conditional relevances in their forward and backward orientation, in the sense that each utterance form in the dynamic flow of discourse is the expression of its functional and structural values.

Diglossia

A. Hudson

The term 'diglossia,' was introduced into Anglo–American sociolinguistic scholarship in 1959 by Charles A. Ferguson. In Ferguson's formulation, diglossia refers to 'a relatively stable language situation in which, in addition to the primary dialects of the language (which may include a standard or regional standards), there is a very divergent, highly codified (often grammatically more complex) superposed variety, the vehicle of a large and respected body of written literature, either of an earlier period or in another speech community, which is learned largely by formal education and is used for most written and formal spoken purposes but is not used by any sector of the community for ordinary conversation' (1959: 336).

1. Characteristics, Origins, and Evolutionary Course of Diglossia

Ferguson proposed a set of nine features by which diglossia might be identified and distinguished from other sociolinguistic situations:

(a) the superposed variety (H) and the vernacular variety (L) are in strict complementary functional distribution;

(b) H is uniformly held in higher esteem than L by members of the speech community;

(c) H has associated with it a substantial and highly regarded body of written literature;

(d) proficiency in H is typically attained as a result of formal schooling, whereas proficiency in L is attained through the natural process of mother-tongue acquisition;

(e) the pronunciation, grammar, and vocabulary of H are standardized and tolerate only limited variation, whereas there is wide variation in the pronunciation, grammar, and vocabulary of L;

(f) diglossic situations are extremely stable, and typically persist for several centuries at least;

(g) there are always extensive differences between the grammatical structures of H and L;

(h) there exists a series of phonologically unrelated lexical doublets for concepts frequently expressed H and L; and

(i) the sound systems of H and L constitute a single phonological structure of which L is the basic system (Ferguson 1959: 328–36).

Diglossia is distinguishable from the typical instance of a standard with dialects (see *Dialect and Dialectology*) in that 'no segment of the speech community in diglossia regularly uses H as a medium of ordinary conversation' (1959: 336–7). Likewise, diglossia is clearly to be distinguished from 'the analogous situation where two distinct (related or unrelated) languages are used side by side throughout a speech community, each with a clearly defined role' (Ferguson 1959: 325 n.2).

Ferguson rejected the proposition that diglossia occurs 'always and only at a certain point in some kind of evolution' (1959: 326–7), and instead took the position that 'diglossia may develop from various origins and eventuate in different language situations' (1959: 327). Nevertheless, diglossia is particularly likely to evolve (a) when there exists a sizeable body of literature in the language of the community, or in a language closely related to it, which embodies the fundamental values of the community; (b) when literacy in the written variety is limited to a small elite; and (c) when a protracted length of time, on the order of several centuries, has elapsed between the formation of a literary tradition and the democratization of literacy (see *Literacy*; see also Ferguson 1959: 338). Although the diglossic system represents an inherently stable situation once fully matured, its disintegration is frequently accompanied by tendencies toward more widespread literacy, greater communication across social and regional boundaries, and a heightened sense of linguistic nationalism (see *Nationalism and Language*; see also Ferguson 1959: 338). In the aftermath of diglossia, H most typically 'fades away and becomes a learned or liturgical language studied only by scholars or specialists and not used actively in the community,' while some form of L, or a compromise between H and L, replaces H as the standard (Ferguson 1959: 339).

2. Incidence of Diglossia

Diglossia, so Ferguson has claimed, has probably occurred hundreds of times over the course of history, and is realized in dozens of instances in the modern age (1959: 338).

Diglossia has been described as a sociolinguistic areal feature of South Asia, and has been reported for Bengali (Chatterjee 1986) and Sinhala (Gair 1986), as well as for Kannada, Malayalam, Tamil, and Telugu (Bright and Ramanujan 1972: 158, Britto 1986). Whether Sanskrit ever coexisted with any of its Indo–Aryan relatives in a diglossic relationship is a matter of scholarly debate. Sanskrit was still a spoken vernacular in Pāṇini's time (ca. 500 BCE), but had become a superposed, scholarly variety by the first century BCE, the mass of the population then being proficient in Prakrit only (Deshpande 1986: 315, 317).

Diglossia appears to have existed in China since about the first century CE (Norman 1988: 4, 248–9), and in Japan since at least the seventh (Coulmas 1987: 115–6). The centuries-old three-way opposition between classical written Chinese, vernacular written Chinese, and vernacular spoken Chinese represents an instance of diglossia, or even triglossia, par excellence. Classical Chinese remained the predominant medium for official documents and for literary and philosophical writing intended for the consumption of the educated ruling classes until the fall of the Qing dynasty in 1911 (Barnes 1982: 262).

Classical Chinese was also employed as the earliest medium for writing in Japan (Coulmas 1991: 129, Habein 1984: 3). Beginning around the seventh century CE, with the incorporation of Japanese words not translatable into Chinese and of Japanese syntactic patterns, this system was gradually nativized, becoming distinct from the Classical Chinese model while at the same time remaining vastly different from spoken Japanese (Coulmas 1991: 129; Habein 1984: 8–10). This style of writing, known as '*kan-bun*,' was to remain the style 'in which every respectable book was expected to be written until the Meiji Restoration' (Coulmas 1987: 125 n. 8). A more indigenous system of writing Japanese, known as '*wabun*,' which employed the native Japanese *hiragana* syllabary as well as Japanese vocabulary and syntax, was begun some time in the ninth century and perfected by the eleventh; however, although this style of writing initially reflected the spoken language of the period, its basic grammar remained similar to that of the eleventh century, even up until the end of the nineteenth century (Coulmas 1991: 133, Habein 1984: 3–4, 28). By the end of Meiji era in 1911, however, most literary prose was being written in a style much closer to colloquial Japanese.

While some scholars maintain that diglossia in Arabic emerged with the Islamic conquests of the seventh century CE (Blau 1977: 182, 190), others hold that the language of pre-Islamic poetry was radically different from that of the colloquials, and so trace the roots of Arabic diglossia to a period predating the rise of Islam (Altoma 1969: 4, Rabin 1955: 26). Classical Arabic, however, had ceased to be a spoken variety, and had become a purely literary idiom, by the end of the Umayyad caliphate in 750 CE (Rabin 1955: 20). Classical Arabic is still used for religious purposes, and is formally taught in schools, particularly in preparation for the study of religion or the study of the Arabic language and Arabic literature (Cadora 1985: 74). Modern Standard Arabic, a modernized and somewhat simplified derivative of Classical Arabic, has become the medium for serious writing, broadcasting, and formal public speaking, and one or other variant of colloquial Arabic, substantially different in structure from the latter, is

employed in all informal interaction (Cadora 1985: 75–6).

Diglossia is also to be found in several other Semitic languages. In Palestine, from about 1000 BCE, spoken Hebrew differed significantly from the Hebrew used in the composition of the Old Testament (Fellman 1985: 28, Rendsburg 1980). The latter variety was used for prayers and formal literary composition, while all normal discussion and teaching of religious matters took place in the former (Spolsky 1991). In Ethiopia, the Ge'ez language, which died out as a spoken language between the ninth and the thirteenth centuries, remains in active use as the language of worship and sacred literature in the Ethiopian Orthodox Church, although as a language of literature it has now largely been replaced by Amharic (Bender et al. 1976: 99–100).

Although the language and dialects of oral and written literature in Greek have always differed from the vernaculars, the years following the Roman conquest saw the rise of a movement to replace the Hellenistic koiné, by then the normal medium for all prose writing, with the classical Attic Greek of the fourth century BCE (Alexiou 1982: 179–80, Browning 1982: 48–50). Up until the end of Ottoman rule in 1821, colloquial varieties of Greek were employed for literary purposes only in peripheral areas of Greek influence or in works of popular edification, not for serious literature in the core areas of Greek cultural influence (Browning 1982: 52). With the establishment of the new Greek state in 1830, an artificially classicized and 'purified' variety of Greek, known as '*katharévousa*,' was adopted as the national language, and as the language of civil government and public education (Browning 1982: 53–4); by contrast, the gradual industrialization of Greece, the birth of a nationalist ideology, and the demands for an effective system of public education in the nineteenth century resulted in popular support for colloquial Greek, known as '*demotiké*' (Browning 1982: 56). Since the fall of the last military junta in July 1974, *demotiké* has been adopted as the official language of the Greek state, and a decisive expansion of the latter into domains formerly regarded as the preserve of *katharévousa* has taken place (Browning 1982: 58).

The seeds of diglossia in Latin may be identified in the second and first centuries BCE with the differentiation of written Classical Latin from the popular spoken variety and the emergence of a Latin literary standard (Hall 1986: 215). From about 100 BCE to 400 CE, Classical Latin was widely understood (Pei 1976: 49, 55), although its mutual intelligibility with popular Latin was decreasing steadily (Hall 1986: 213). Later, the functional complementarity between Classical Latin and the early vernacular Romance varieties, combined with the decline in the rate of popular literacy, set the stage for diglossia (Hall 1978: 102, 109). Latin–Romance diglossia of the

227

ninth century was buttressed for a time by Charlemagne's efforts to reform the pronunciation of Latin among the clergy but, by the thirteenth and fourteenth centuries, the growth of urban commercial activity, the decline in the relative importance of the clerical orders in secular administration, and the development of oral and written poetry in the vernacular had begun to fuel the expansion of the Romance vernaculars into virtually all domains of interaction (Parker 1983: 336, 338–40).

Instances of classical diglossia may be found at various times in Persia, the Slavic lands, and Ottoman Turkey. By the end of the seventh century CE, Middle Persian, or *parsi*, had become markedly different from spoken Persian, or *dari*, and had become the medium of administration, religion, and written literature, while *dari* remained the language of everyday oral communication, (Jeremiás 1984: 273, Lazard 1975: 596, 598–9). In Russia, the introduction of writing along with Christianity in the tenth century CE, gave rise to diglossia between vernacular Old Russian and a partly Russianized version of Old Church Slavic (Comrie 1991: 161, 165–8). Old Church Slavic was the language of the Orthodox liturgy and of the Old Russian chronicles, although the reported speech of the latter, and legal documents of the period, contain almost exclusively vernacular forms (Comrie 1991: 165–6). In the late twentieth century, Russian Church Slavic is the language only of the Russian Orthodox liturgy, although its influence on Modern Standard Russian vocabulary is pervasive, particularly in religious and more learned and abstract domains (Comrie 1991: 169). Finally, in sixteenth-century Ottoman Turkey, the court and literary varieties of Turkish began to diverge from the vernacular, becoming maximally distinct early in the eighteenth century (Karpat 1984: 189, 190–1). By the end of World War I, however, Ottoman Turkish, or *osmanlica*, had become completely moribund and was being replaced by a new standard based largely upon the spoken language of the educated classes of Istanbul and the larger cities (Gallagher 1971: 163).

The best known case of diglossia in Western Europe is that between Swiss German and Standard High German in Switzerland. High German, as the liturgical language of Protestantism, the German literary language, and the language of higher education, became the unquestioned norm in the domain of high culture throughout the German-speaking lands (Schiffman 1991: 178). However, whereas *Hochdeutsch* in time began to displace local dialects of German as a mother tongue in Germany, in Switzerland, antipathy toward nineteenth- and twentieth-century German expansionism has resulted in the relegation of *Hochdeutsch* to written and formal spoken functions only (Barbour and Stevenson 1990: 215, Keller 1982: 87–8). A similar diglossic situation

is said to exist in Liechtenstein, where Standard German is the language of administration, parliament, the courts, religious services, and education (Clyne 1984: 18). Yet another instance of diglossia exists in Luxembourg between Standard German and *Letzebuergesch*, with French as an additional high variety (Clyne 1984: 20–1, Barbour and Stevenson 1990: 230–4, Keller 1982: 73).

It seems not to have been recognized that classical diglossia has also existed in Irish and in Welsh. Although a case might well be made for diglossia in the Old Irish period of the eighth and ninth centuries (Ó Murchú 1985: 38), a clearer case is the emergence, around the beginning of the thirteenth century, of a single, tightly controlled, universally accepted, national literary language (Corkery 1968: 41). From the thirteenth to the seventeenth centuries, three main literary styles of Irish could be distinguished, all of them significantly different from the popular vernaculars of the day: an archaizing style used primarily in historical and pseudohistorical writings; a mainstream literary usage known as 'the poets' standard'; and a relatively more casual norm possibly based on the spoken language of the educated classes (Ó Murchú 1985: 42). In Welsh, from the twelfth through the fourteenth centuries, the literary works of the court poets, characterized by deliberate archaism in vocabulary and syntax, became the norm for the Welsh literary language, as did the language of their successors, the poets of the nobility, from the fourteenth century until the sixteenth (Jones 1988: 126–7). With the translation of the New Testament into Welsh in 1567, and subsequently the translation of the entire Bible, yet another literary standard for Welsh was born, one which was again substantially different from the Welsh of casual social interaction, and one which exercises considerable influence on written Welsh even up to the present day (Jones 1988: 128–31).

3. Typology

No single effort to extend, to narrow, or to differentiate Ferguson's definition of diglossia has been as profoundly influential as Joshua Fishman's essay on the relationship between bilingualism and diglossia (1967) and its various revisions over a period of more than 20 years (Fishman 1970, 1980, 1985, 1989). As defined by Fishman, diglossia is '*an enduring societal arrangement*, extending at least beyond a three generation period, such that two "languages" each have their secure, phenomenologically legitimate and widely implemented functions' (1980: 3). The 'languages' in question may be distinct languages or varieties of the same language which are sufficiently different from one another that, without schooling, the elevated variety cannot be understood by speakers of the vernacular (Fishman 1980: 4). Diglossia is the 'stable, societal counterpart to

individual bilingualism' (Fishman 1980: 3) in that, while the latter is 'a characterization of *individual* linguistic versatility' (Fishman 1970: 83), the former represents 'a well understood and widely accepted social consensus as to which language is to be used between which interlocutors, for communication concerning what topics or for what purposes' (Fishman 1967: 34).

Fishman's account of diglossia differs from Ferguson's in two significant respects. First, whereas Ferguson restricts the definition of diglossia to situations where the codes in question (see *Code, Sociolinguistic*) are strikingly divergent varieties of the same language, Fishman, although limiting the definition to 'significantly discrepant...varieties,' nonetheless includes within its compass situations where the elevated and vernacular varieties are genetically unrelated (1980: 4). Second, Fishman, unlike Ferguson, recognizes two types of compartmentalization of codes in diglossia: a functional compartmentalization, where different codes are assigned by social consensus to nonoverlapping speech contexts within a single speech community; and a territorial or political compartmentalization, where codes are distributed along population lines within social or political entities comprised of multiple speech communities (Fishman 1967: 33, 1980: 7–8).

Fishman's 1980 account of diglossia differs from Ferguson's in recognizing four major categories of diglossia based upon the linguistic relationships between the elevated and vernacular varieties within the code matrix. Ferguson and Fishman both recognize a classical variety of diglossia exemplified by the Arabic and Greek cases, as well as a category, represented by Swiss–German diglossia, where the elevated code is not a classical variety, but rather a written or formal spoken norm in functional opposition to the 'significantly discrepant' variety of spontaneous discourse (Fishman 1980: 4). However, Fishman departs from Ferguson in distinguishing between those instances of diglossia in which the high variety, whether classical or not, is a structural variant of the vernacular and those cases where it is not. Thus, the case of Hebrew and Yiddish in many Jewish speech communities is advanced as an instance of a classical variety in diglossic partnership with an unrelated informal variety, while the case of Spanish and Guaraní in Paraguay is advanced as an example of a nonclassical, formal, or written norm in a diglossic relationship with a genetically unrelated indigenous vernacular.

Fishman's extension of the term 'diglossia' to include cases where the elevated and vernacular varieties are not genetically related in any immediate sense has led to numerous efforts to develop a typology of diglossic situations. Most commonly, the degree of relatedness between the codes in the speech repertoire has formed the principal axis along which the various types have been differentiated. Thus, Kloss distinguishes between in-diglossia, or *Binnendiglossie*, referring to diglossia between genetically related codes, and out-diglossia, or *Aussendiglossie*, referring to diglossia between genetically unrelated codes (1976: 316). Timm (1981: 363–4) and Pauwels (1986: 15) capture the same distinction with the terms 'intralanguage diglossia' and 'interlanguage diglossia.' Fasold (1984: 52–4) uses the term 'broad diglossia' to subsume the categories of 'superposed bilingualism' in the case of distinct languages, 'classic diglossia' in the case of significantly discrepant varieties of the same language, and 'style shifting' in the case of minimally differentiated stylistic variants. This same tripartite division surfaces again in Britto's terminological distinction between 'superoptimal codes,' 'optimal codes,' and 'suboptimal codes' (1986: 10).

Among the various typologists of diglossia, Britto and Pauwels, in particular, note the importance of the nature and degree of social compartmentalization of codes as an axis of classification orthogonal to that of structural relatedness. For his part, Britto distinguishes between situations where the varieties in question are used by separate speech communities having no direct linguistic contact with each other, situations where the dialect of one particular region or social group is used as the standard variety by speakers of other dialects, and situations where a single community uses two or more distinct codes for within-group communication, each with its own particular range of functions (Britto 1986: 35–40). Britto refers to the first of these categories, where there is no within-group differential functional allocation of codes, as 'pseudodiglossia'; to the second, where the elevated or standard variety is not a superposed variety for all members of the larger community, as 'user-oriented' or 'dialectal diglossia'; and to the last, akin in this respect to the classical diglossia of Ferguson, as 'use-oriented' or 'diatypical diglossia' (1986: 35–40). Pauwels makes a comparable distinction between situations in which virtually all of the members of a speech community learn the elevated variety as a superposed variety, which she refers to as 'general diglossia'; and situations, which she labels 'partial diglossia,' in which only a substantial proportion of the members of a speech community acquire the high variety as a superposed variety (1986: 15). Pauwels also distinguishes between 'rigid diglossia,' in which there is minimal functional overlap between codes, and 'fluid diglossia,' in which some functions, at least, are less rigidly associated with a particular code (1986: 15).

The proliferation of diglossia types, and the many attempts to systematize these types within a general classification, reflects the multiple ambiguity which has crept into the use of the term since it was first

employed by Ferguson in 1959. It is this ambiguity that is in large measure to blame for the often conflicting points of view which different scholars in the field hold with regard to the origins, evolutionary course, and social consequences of diglossia. There is little prospect of progress on these issues until such time as a single definition of diglossia is adopted to the exclusion of all others, or, until the various subcategories of broad diglossia are expressly and consistently identified in any theoretical treatment of the phenomenon. There is little agreement on how to proceed. Fasold (1984), Britto (1986), and Pauwels (1986) advocate the use of the term 'diglossia' in a general sense to refer to a situation where a speech community makes use of high and low variety ranges, each with its distinctive functional allocation, and where the high variety, or repertoire of varieties, is customarily acquired later in life, normally through the process of formal schooling. Others, including Hudson (1991: 16), advocate a return to the essence of Ferguson's original definition.

The most comprehensive bibliography on diglossia, containing more than 3,000 entries, is that by Fernández (1993). A shorter bibliography was published by Hudson (1992). A special issue of the *International Journal of the Sociology of Language*, focussing on diglossia, is scheduled to appear in August 2002.

Discourse Analysis and the Law

D. Eades

1. Introduction

The term 'discourse analysis' is used in a wide range of meanings. In this entry it is used with the traditional meaning of the analysis of language beyond the level of the sentence, namely that level of linguistic analysis that complements phonetics, phonology, morphology, syntax, and semantics. In this sense, the term is sometimes seen to correspond to the broader meaning of the term 'pragmatics' (see *Pragmatics and Sociolinguistics*).

In legal contexts, discourse analysis is generally carried out in order to shed light on questions of sociolegal significance. Most studies to date have analyzed language in courtrooms, where access to data is much easier than in other legal contexts, such as police or lawyer interviews. Most of the literature on this topic written in English deals with the adversarial legal system, found in countries such as the UK, the USA, Australia, and other Anglo countries. The particular methodological approaches used include ethnography, formal linguistic analysis, critical discourse analysis, conversation analysis, and interactional sociolinguistics. (See *Conversation Analysis*; *Critical Sociolinguistics: Overview*; *Ethnography of Speaking*; *Interactional Sociolinguistic Research Methods*.)

2. Courtroom Discourse

One of the earliest studies in this area addressed the influence of language factors on legal decision-making. The linguistic anthropologist W. M. O'Barr and lawyer John Conley headed the Duke University Language and Law Project, focusing on different speech styles used by witnesses in US courtrooms in the late 1970s. They combined an ethnographic study to find out about variations in language forms, with a psycholinguistic experimental study to find out the effects of these variations in form on trial processes. Their ethnographic study found that witnesses tend to use one of two different styles, termed 'powerful' and 'powerless.' The powerless style is characterized by many of the features which had earlier been said to typify women's speech, such as a high frequency of intensifiers (e.g. *very, really*), and the use of hedges (e.g. *sort of, like*). The powerful style, on the other hand, without such linguistic features, sounds much more precise and confident. And the experimental study found that witnesses using the more powerful style were considered by jurors to be more convincing, truthful, competent, intelligent, and trustworthy than those using the powerless style were. So, it is clear that the details of the way in which witnesses

231

present their evidence can be very important to the outcome of a case.

The concern in the Duke study with the relative power (or lack of power) of witnesses has remained central to many of the more recent studies. A number of these have demonstrated the strong power imbalance between a witness on the one hand, and a lawyer and a judge/magistrate on the other, exemplified in such discourse features as these:

(a) witnesses are typically asked a large number of questions requiring a minimal response;

(b) witnesses say very little compared to the verbosity of those questioning them;

(c) the majority of questions put to witnesses contain already completed propositions; and

(d) witnesses are not in control of telling their own story.

The greatest imbalance occurs in hearings in which the witness is a second language or nonstandard dialect speaker, or a child.

A particular focus of studies of language and power in the courtroom starts with the knowledge, which is common to lawyers and police officers, that some types of questions allow the interviewee more freedom, while others are much more restrictive. Through careful choice of the actual question structure then, lawyers have powerful linguistic means for being conducive, controlling, coercive, or manipulative. By examining the answers logically expected from the structure of the questions, and in some cases, by also looking at the actual answers elicited, a number of linguists have organized question types into courtroom 'hierarchies of control.' These hierarchies show that the most controlling questions are Yes–No questions with a tag (e.g., *You were at the beach that day, weren't you?*), and the least controlling are broad WH questions (*why, what, how*). Thus it is not surprising to find that most cross-examination is dominated by Yes–No questions, many of them with tags, while there are typically more WH questions in examination-in-chief (= direct examination).

But there is more involved in the exercise of power and control in the courtroom than simply question type: for example, depending on intonation, a tag question could be an extremely pressured and harassing act, or it could be one of simple verification. And indeed, in examination-in-chief the so-called most controlling questions can be taken by witnesses to be invitations to explain. In this way, for example, a question with a Yes–No tag structure may *function* as if it is a broad WH question.

In addition to question structure, researchers have found a number of other linguistic strategies

used by lawyers to exercise control over witnesses, including:

(a) interruptions;

(b) reformulation of witness's descriptions of events or people (e.g., from *my friends* to *a group of louts*);

(c) manipulation of lawyer silence, for example with the use of strategic pauses;

(d) nonrecognition of some witnesses' need to use silence as part of the answer, which can be particularly important, for example, for Australian Aboriginal witnesses;

(e) incorporation of damaging presuppositions in questions (such as *Did you all laugh while the car was being thrashed?*);

(f) metalinguistic directives given to the witness (such as *You must answer this question*); and

(g) management of topics in order to convey a particular impression to the jury.

A particular concern which arises from detailed discourse analysis of both rape cases and child sexual assault cases is that the courtroom hearing may be so manipulative of the witness and so traumatic, that the process of giving evidence actually amounts to revictimization of the victim-witness.

2.1 Second Language and Non-standard Dialect Speakers

An important issue in the investigation of power imbalance in the courtroom concerns the situation of witnesses who do not speak the language of the court. In many countries, there is a growing awareness of the need to provide interpreters. Discourse analysis of interpreted proceedings has shed light on the way in which legal interpreters function, which has important implications for the training both of interpreters and of legal professionals who work with them. The most important work in this field contradicts the predominant legal perception of the interpreter as a conduit or 'language machine' through which language is processed. Instead, detailed discourse analysis by Susan Berk-Seligson and others shows that the interpreter is an important courtroom participant, whose job involves much more than translating propositional content. The interpreter must also be finely tuned to the subtleties of pragmatics, distinguishing for example between different types of English tag questions used in cross-examination for different pragmatic purposes.

While second language speakers often have access to interpreter services, the situation of non-standard dialect speakers' access to justice is more complex. Communication difficulties, while not as extreme as with second language speakers, are compounded by the general lack of recognition of nonstandard dialects, combined with frequent prejudice against such dialects and their speakers. Most of the research

on speakers of nonstandard dialects in legal contexts has focused on Australian Aborigines, whose imprisonment rate is the highest recorded for any ethnic group in the world. Discourse analysis of Aboriginal English speakers in legal contexts highlights a number of pragmatic features which are largely unrecognized or misinterpreted, and which clearly affect their dealings with the law. For example, in contrast to the Anglo legal system and society generally, where silence in an interview is generally taken to mean that a speaker has nothing to say, many speakers of Aboriginal English (as well as traditional Aboriginal languages) use silence as a positive and productive part of communication. Thus, Aboriginal English silence is often the first part of the answer to a question, and it can signal that the speaker considers the question important enough to warrant serious consideration before speaking.

3. Lawyer–Client Interviews

While interaction between lawyers and their clients forms an important legal context, there is to date little discourse analysis of these interactions. Research has so far investigated the ways in which lawyers make sense of the legal process for their clients, and has found that there are quite different ways of seeing the client's problem. Lawyers tend to be focused on legal rules and the categories both of law and of legal problems. Their clients, on the other hand, tend to be more oriented to telling their story. Interestingly there appears to be little difference between the way that male and female lawyers talk to their clients. However, both male and female clients are more deferential to male lawyers than to female lawyers.

4. Police Interviews

Analysis of police interviews has primarily focused on interviews with suspects and has addressed the important legal issue of the comprehensibility of the police caution (about the rights of a suspect, known in the USA as the Miranda Rights), as well as the questions put to suspects. Researchers have found that the typical wording of the Miranda Rights requires the equivalent reading skills of a tenth grade high school student. In Australia, linguists have presented expert evidence analyzing nonnative speak-ers' difficulty in understanding both the caution and certain questions in specific police interviews. And further, several linguists have been involved in projects to simplify the wording of the police caution and to translate it into a number of local indigenous languages.

5. Conclusion

Work on discourse analysis in the law has some immediate practical relevance, in examples such as those discussed above. In addition, expert linguistic evidence is increasingly being provided by some scholars in the analysis of language, which is used in evidence in criminal cases. Such use of linguistic analysis as expert evidence is dealt with in the article *Forensic Phonetics and Sociolinguistics*. (Note that this term is also sometimes used more broadly to refer to linguistic studies of language in legal contexts.)

Discourse analysis in legal contexts is a relatively new field of study, and one that involves not just description and analysis of this specialized area of language use. Sociolinguists are increasingly using detailed microanalysis of the way that language is used in the legal process, to help shed light on exactly how it is that the legal system often fails to provide justice.

Formulaic Language

F. Coulmas

'Formulaic language' is a cover term for ready-made constructions which can be used without having to be built up from scratch. Various kinds of formulaic locutions such as proverbs, similes, and other loci communis were traditionally treated in Rhetoric or Stylistics. Jespersen (1924) was the first to make a general distinction between 'formulas' and 'free expressions' which 'pervades all parts of grammar.'

233

Free expressions are created in each case, whereas formulas are drawn from memory. Formulaicity is considered by some scholars (e.g., Bolinger 1976) to be a basic property of language which makes it unnecessary to fully exploit for every utterance the productivity of grammar and, at the same time, curtails it. Formulaic speech is believed to be a universal phenomenon found in every speech community.

1. Kinds of Formulaic Expressions

The four main types of formulaic expressions are (a) fixed phrases for daily use, (b) ritualistic formulas, (c) routine formulas, and (d) poetic formulas. Each of these encompasses a great variety of subtypes.

Fixed phrases include idioms ('a red herring'), phrasal verbs ('to drive something home'), standard metaphors ('iron curtain'), binominals and other paired items ('part and parcel,' 'alive and kicking,' 'on and off'), collocations ('beyond reproach'), conventional similes ('she is like a rose'), clichés ('the good old days'), slogans ('Ha!. Liberté, égalité, fraternité'), curses, familiar quotations (Shakespeare's 'tooth of time').

Ritualistic formulas are characteristic of explicitly prescribed language use, for example in religious exercise including blessings, absolutions, vows; magic incantations; law, as in contract formulas; and government, e.g., oath of office, public announcements, diplomatic invitations.

Routine formulas, also called 'pragmatic idioms,' comprise fixed expressions for highly recurrent communicative tasks such as salutations, introductions, thanks, apologies, excuses, compliments, toasts, epistolary beginnings and closings, as well as conversation management, e.g., claiming, passing or soliciting a turn, interrupting, introducing a topic, requesting repetition or explication, closing a topic or conversation.

Poetic formulas are phrases which are repeated in the same form whenever an idea or person is mentioned in an epic. They include stock epithets ('Achilleus of the swift feet') as well as longer phrases which have been employed as tools of metrical composition.

2. Properties of Formulaic Speech

The formulas of a language are generally known by its speech community and distinguished by their popularity and conventionality. Some can be recognized, even if they are not known as formulas, on the grounds of formal peculiarities. From the point of view of grammar, formulaic speech is conspicuous because of the non-generative nature of many formulaic expressions. Although they exhibit an internal structure, they are not generated by the rules of ordinary syntax. They violate syntactic rules or exemplify obsolete rules which have become unproductive. As a result, their structures are unique or arbitrarily restricted in productivity and distribution. Syntactic patterning and semantic composition are not matched. Many formulas are therefore semantically not transparent since their meanings are not deducible from their structures.

These features of speech formulas—that is, frozen structure, semantic opacity, and syntactic deviance—are graded rather than categorical properties, and hence formulaicity itself is a graded notion.

3. Functions of Formulaic Speech

The psycholinguistic significance of formulas is that they are stored and retrieved whole, hence serving a function in speech production of easing the pressure of simultaneous planning and execution of long stretches of speech. Like other automatisms, pre-patterned formulas drawn from memory as stock items, save time for planning. There is evidence that the ability to produce fluent speech depends partly on a sufficiently large stock of formulas (Pawley and Syder 1983), although not every expression which has formulaic qualities for an individual speaker is necessarily recognized as a formula by the speech community at large. That there is a distinction between individual and social formulas is underscored by observations of language acquisition. It was found that in both first and second language acquisition 'unanalyzed chunks of speech' (Peters 1983) are stored in the memory and accessed as such, some of them formulas of the language, others formulaic items of an idiosyncratic nature. These functions of formulaic speech raise important questions about the units of language to be accounted for in a performance model.

From a sociolinguistic point of view, formulaic speech incorporates sociocultural knowledge. For handling many recurrent communicative tasks characteristic of a society or social group the appropriate expressions are socially recognized formulas (Coulmas 1981). In that they embody accepted ways of responding verbally to a variety of situations, they facilitate social relations and thus have an adaptive value. Since they are indicative of conventions and etiquette, they are a means of social control. Many situations leave very little choice for the 'right word.' Using the expected formulas is a strong indication of belonging, social identity, or acculturation. Their knowledge creates and reinforces social cohesion.

Formulas also fulfill functions on the interaction level, especially for discourse control. As metacommunicative signals formulas are used to define the nature of a conversation, to establish an agenda of topics, to steer the flow of discourse from one stage to another, to distribute speaking rights, and to indicate cognitive attitudes, such as belief, surprise, disagreement.

As regards their poetic functions speech formulas are mnemonic devices used for handing down from one generation to the next, in poetic form, knowledge and beliefs, indicating the traditional conceptualizations of man and the universe (Watkins 1989). Much attention has been paid to formulas in the study of oral literature (Lord 1960, Duggan 1975), because their pervasive occurrence there can explain how lengthy works of poetry could be remembered without written recording.

Genre
T. Threadgold

'Genre' was originally a literary term. Its history in literary and rhetorical studies continues to mark the associations that it has come to have with literature and pedagogies of literacy (the teaching of reading and writing). The literary background is also evident in the extension of genre into anthropology and cultural studies; into ethnography, sociolinguistics, critical discourse analysis, and social semiotics, which have sought to provide explicit linguistic and contextualized accounts of the functions of genres in a wide variety of social practices and sites. It also has strategic uses in feminist and poststructuralist literary and cultural theory where it functions as the locus of textual transgressions designed to restructure the disciplines, and as a means of understanding and attempting to change the sociocultural construction and transmission of patriarchy.

1. Overview of Genre Theories and Classifications

All these enterprises are still marked by the Aristotelian literary origins of the genre concept, along with a metaphysics and an epistemology which derive from Aristotle's natural philosophy, and a link (implicit in Aristotle) between the philosophy of Natural Kinds, genres as kinds of texts, and sociocultural classes of people (Hauptmeier 1987). Biological metaphors, introduced into genre studies by aspects of Aristotelian naturalism which reached its epitome in the taxonomies of Linnaeus, are as significant in the construction of later genre theory as are the Aristotelian metaphysical and social metaphors. Just as the discipline of biology overcame the dualism between naturalism and conventionalism

with the development of evolutionary theory, which provided a way of both motivating classifications and freeing fixed essences to historical development, so genre theory, in the work of the Russian Formalists, the Prague School, Bakhtin (see *Dialogism*); the Tel-Aviv School of Poetics, and reception theory, to name only the major influences, turned to theories of evolution and of interaction between texts and environments to explain and motivate systems of 'kinds' (text types and literary systems) and changes in those systems. Questions of literary genre and biological taxonomies are historically connected in Aristotelian thought, and genre and biology, genre and gender, or genre and sexuality, are etymologically connected in the ambiguity of genre in French. This history and the dominance of these metaphors and connections have only begun to be explored: late twentieth-century poststructuralist and feminist work has sought to demonstrate the conventional, socially constructed nature of both genre and biology, and to explore the complex relations between genre and gender, genre and power, genre and institutions, genre and discipline, and genre and the teaching of literacy.

There have always been implicit or explicit social, aesthetic, and even moral values associated with the classification of genres. The earliest classifications of Classical poetics and rhetoric into high, middle, and low kinds are typical: they assume an implicit homology with a sociocultural classification of kinds of people according to the modes and styles of speech or writing which characterized them (Fowler 1982: 240 ff.). These early classifications later become the

high/popular culture distinction. Hierarchies of genres and social and moral values, whether part of an explicit or covert pedagogy, are essential to the business of canon formation, and to the institution of literary study and of literacy (which is a technology for social control: see Hunter 1988). The historically constant classification of genres associated with the most powerful social and cultural institutions of government, religion, law, and pedagogy (and thus literature and science) as 'high' has also contributed to the establishment of the distinction between national standard languages and 'nonstandard' languages; to the construction and maintenance of current disciplinary structures in schools and universities; and, many would say, to all kinds of global, national, social, ethnic, racial, and gender inequalities.

Genres, in most analyses, are considered to have specific forms which organize the matter or substance of which the genre is made. The form may impose a subject matter, a manner or mode, and a typical text structure. Forms themselves can be classified. One typical classification of kinds or forms derives from Aristotle's *Poetics*, mediated by Cicero and Quintilian, the normative rhetorics and poetics of the sixteenth centuries, and the neoclassical rhetorics and poetics of the eighteenth and early nineteenth centuries. This survives in the organization and teaching of literary studies, and in rhetorical approaches to the teaching of writing. The classification into lyric, dramatic, and narrative, which is basic to the division of literary texts into the 'kinds' of poetry, the novel, and drama, is at least as old as Plato and Aristotle, and still functional in many places.

In literary and rhetorical uses of such classifications, each kind will be characterized by particular topics (the *topoi* of Classical rhetoric), modes (such as narrative, allegory, satire), forms of argumentation (the deliberative, the epideictic, the forensic, for example, ancestors of the modern expository, descriptive, and legal), and styles—high, middle, low. These are associated with varying distributions and uses of the figures of rhetoric, e.g., metaphor and metonymy, which still serve to separate the literary from the ordinary in style and language; and methods of organization (*dispositio*, what are often called schematic structures). The most typical of all such schemata of textual organization is the Aristotelian one of the text which must have a beginning, a middle, and an end, the prototype of the texts explored in narratology (Coste 1989), a text defined by its internal conflict, climax, and denouement, and by the rational synthesis which produces its closed, complete, and coherent structure.

Fowler (1982) argues that knowledge of genre, for the classically educated, provided the framework for a recognition of 'allusion' and generic patterning in texts, a recognition of the system of values associated with the system of genres, and an explicit pedagogy for, and practice of, literary criticism and writing and reading. Explicit genre-based rhetorics have also always tended to stabilize the relations between production and reception of texts, so that mismatches between the codes used to produce and to receive—formalized by Eco (1976), and alluded to in Fowler's account of the decline of Classical education and its effect on the reading of earlier texts—are minimized and controlled.

Some of the most interesting aspects of literary rhetorical theories of genre are the evolutionary tendencies to be found associated with the terms 'kind' and 'mode,' which Fowler says are both 'generic' terms, or ways of defining genre. He suggests that 'kind' is a nominal term, and 'mode' an adjectival or modulating one, and that the two are used together to characterize combined or mixed genres such as the pastoral elegy or the heroic epic. Mode, however, is always dependent on kind, and modes are derived or evolved from kinds. Thus, kinds such as epic, biography, tragedy, and comedy can be realized as modes—epic, biographical, tragic, comic—within other genres. So the gothic 'kind' can be extended as a 'mode' to modulate the kinds of the crime novel, the short story, the film script, or science fiction. Fowler argues that literary genre theory, still influenced by Romanticism, has been dominated by modes (romance, lyric, narrative, dialogic, dramatic, tragic, comic), not kinds, because the modes are less formally and historically circumscribed than the kinds, which tend to be linked to specific social institutions and practices. There is in this an implicit recognition of the ubiquity of modes like narrative and dialogue in all kinds of other genres and media, and of the difference between narrative, dialogue, and genres (Coste 1989, Jauss 1989, Swales 1990 calls narrative and dialogue 'pre-genres'). The literary theory anticipates later poststructuralist accounts of the crucial cultural and socially constructive importance of both narrative and dialogue, and of the multigenericity of many text types (Bakhtin 1968: 86). This is in sharp contrast to linguistic work on genre, which continues to treat narrative as a genre and has rarely explored or recognized the problem of mixed genres.

In all contexts, classifications and theories of genre function both as descriptive/analytical and as prescriptive/pedagogic devices. The use of the term has always included not only descriptions of the characteristics of actual texts, classes of texts, and systems of classes of texts, but also descriptions of schemata assumed to provide guides for the making or writing of texts, whether these are theorized as being in people's heads—formulated as cognitive schemata, knowledge of the world (Hauptmeier 1987)—or as systemic potential modeled from other texts,

formulated as generic structures, generic structure potential (Hasan 1978). Post-structuralism has developed a very different process-based theory of the way in which generic meanings are construed between and across texts in both reading and writing (Kress and Threadgold 1988). The use of genre theory has also extended from models where the understanding of the production and structure of texts was paramount (Marxist, literary critical, and formalist theories) to use in models of text reception and reading: reception theory, semiotics, poststructuralism, and feminism (de Lauretis 1984), where the primary interest is on the interaction between text structures and reading strategies. These may be formulated as reading protocols, codes, or genres of reading, and in the last case involve explicit theories of subjectivity, positioning, embodiment, and discipline (Foucault 1979, Grosz 1989). These theories develop a new rhetoric of intertextuality which, in striking distinction to the old, does not work through the liberal humanist subject as conscious agent, but attempts to describe the way in which practices of reading and writing and of text-making produce that subject and the social world that s/he inhabits. It therefore frames the categories of intertextuality, discourse, genre, and narrative in explicitly political and strategic ways.

Such a theory of genre is a long way from the earlier rhetorical literary theories, but it also shares a good deal with them. In both cases, the theory and the rhetoric of genre has been applied to other semiotic media, visual, architectural, musical, theatrical, and multimedial (Fowler 1982, Coste 1989); in both cases there is a recognition that categories like narrative and dialogism (and probably exposition) are larger, less institutionally and historically constrained than genres; in both there is a narrative of institutional forms constraining and structuring modes and contents; and in both there is a homology between social and generic hierarchy which is potentially disrupted by generic change and transformation.

2. Linguistic Accounts of Genre, and Future Directions

Concepts of genre used in explicitly linguistic (usually sociolinguistic or ethnographic) settings are borrowed fairly narrowly from literary and rhetorical, or structuralist-functionalist sources. The work of Labov (1972) on narratives of personal experience offered a thoroughly Aristotelian schema for the episodic structure of conventional narrative: abstract + orientation + complicating action + evaluation + result or resolution + coda. This was theorized as a regular sequencing of optional and obligatory elements which constituted the 'generic structure of the text' (see *Narrative, Natural*). Similar schemas are elaborated in the tagmemic work on genre (Longacre 1974); and by Hymes on the rhetorical structure of

native American folktales (1981: 106–7). The systemic functional work on genre, primarily in Australia, repeats these schemata for narrative with surprisingly little variation (Martin 1985), and, even when the genre involved is supposedly a different one, such as exposition, the pattern remains very similar. For example, Martin's schema for exposition: Introduction + Body (a series of arguments supporting a thesis) + Conclusion (restates thesis, sums up arguments) (1985: 86) still has the basic Aristotelian pattern of beginning, middle, and end, with the middle involving conflict of some kind that is resolved in the conclusion.

Also rhetorically derived are categories like description, procedure, adhortation, report, explanation (Longacre 1974, Martin 1985). In most cases, the narrative and other labels and schemata are produced *as if* they were motivated by linguistic analysis; but in fact there is a tendency simply to impose a preconceived schema, derived from traditional rhetoric and narratology, on to the linguistic analyses. In other cases, where the schematic elements are apparently motivated by the linguistic analysis, as for example in Hasan's structuralist–functionalist account of the buying and selling genre, there is an equally ad hoc 'naming' of parts which does not tell one very much more than any native speaker could have: that is, the 'names' for the parts of the genre have a folk-linguistic character and are little more than native informant glosses on content.

Such generic schemata seem to represent both the system potential for the making of genres and the classifications of actual text types. The linguistic detail which accompanies such analyses (Wignell et al. 1990), is derived and motivated in its approach, as Swales (1990) points out, from register theory (see *Register*) and often shares its limitations. His criticism of the latter is that its tendency to focus on patterns of language (and on content) as characteristic of 'scientific' or 'legal' or 'media' English, or in the Wignell et al. (1990) case, 'the discourse of Geography,' has had a homogenizing tendency which has inhibited the taking up of issues (the range and variety of genres that actually constitute the institution of the law or science, for example) that have been more readily explored in rhetorically based research on genre. This is why Swales turns to rhetorical theories of genre, derived from literary models, and with a much more complex sense of the relations between texts and their contexts (cf. Bazerman 1988), to complement the linguistic theories in his work on the genres of academic English.

Van Leeuwen's account of 'Generic strategies in press journalism' (1987) offers the kind of combination that Swales envisages, and includes a level of metatheoretical analysis derived from poststructuralism which theorizes the everyday practices that it

investigates. It begins with detailed lexicogrammatical analysis, using Halliday's functional grammar, and motivates the description of the genre of the news story on that basis. The labels which van Leeuwen uses for the 'stages' of his text are carefully derived from and related to the institutional and social contexts and purposes of such texts. They are not derived from preconceived generic schemata or from the linguist's intuitions about 'what is going on' in this text. The interest is in the way in which, in the 'news story,' 'many different, partly contradictory, partly overt and partly covert social purposes are translated into generic structures' (1987: 199). Van Leeuwen identifies the news story as involving subgenres such as 'short reports,' 'features,' and 'editorials,' and including phases of narration, description, exposition, procedure, and adhortation. He is able to bring together native informant type analyses/labelings of genres and modes with explicit linguistic accounts of the ways in which these are realized in parts of an actual text, to describe the way that the text develops in stages according to an institutional and local set of purposes, and to demonstrate that the labeling of the text as 'news story' does not in any way relate to or substantiate its construction as a monologic narrative genre with a typical or single narrative generic schema. In fact, the folk-linguistic label 'story' has to do with the institutional purpose of constructing the news story as primarily factual narrative description and report, in order to disguise the controlling function of the media (its expository, interpretative, and adhortatory purpose). Van Leeuwen argues that there is no evidence for a single generic schema of obligatory or even obligatory and optional stages which could explain the genre of the texts. He sees the structure and production of the texts as better explained in terms of a network of generic choices, which are available within the media as context-specific strategies for realizing the social purposes of journalism in textual form.

The difference between van Leeuwen's work and that of the linguists discussed above is in the degree and depth of contextualization that is involved. His work is not just about language or about narrowly defined text structures derived from folk-linguistic labels. It is a critique and an analysis of those labels, and it is about social structure, cultural realities, socially produced and disciplined agents of social institutions and practices (journalists and the media), and about the very complex relations between what the linguist Halliday called the 'text' and the 'higher order social semiotic' (1978). Halliday's own (1988) work on the contemporary functions and historical evolution of lexical density in science texts, while still within the register tradition of analysis, demonstrates a similar concern with contextualization and the metatheoretical level of critique. Such work in fact involves the same kind of intertextual labour of mapping meanings from text to text which has become the interpretative critical practice of post-structuralist and social semiotic reading practices.

The social semioticians who have also been using systemic linguistics to work on genre, like van Leeuwen, would argue that the three approaches—the functional linguistic, the rhetorical concern with textual histories and families, and the politics and metatheory of intertextuality—are complementary (Kress and Threadgold 1988, Threadgold 1989). All indications are that future work on genre in interdisciplinary and postdisciplinary settings will bring these different but complementary trends together.

Institutional Language
S. Sarangi

'Institutional language' is an umbrella term to refer to our everyday experience of officialese, small print, news-speak, etc., as we fill in official forms, read standard circulars from government and public agencies, and consult legal and medical records. An official memo, for instance, has a recognizable format containing standard abbreviations, forms of address, and even disclaimers such as *Please ignore this request if you have already written to us*. Likewise, a medical case note has a set of identifiable features which distinguish it not only from other institutional documents, such as an affidavit or a bank statement, but also from our acquaintance with written language in the personal sphere (e.g., letters from friends and relatives). We can extend these differences to spoken language use across institutional settings and between institutional and everyday settings.

1. Institutional Language: Problem of Definition and Scope

Based on a principle of dualism, a definition of institutional language can be rendered in negative terms: it is unlike everyday, ordinary language. As Agar (1985) puts it, institutional discourse is 'non-natural non-conversation.' This characterization highlights the fixed, patterned and rule-governed behavior in institutional settings, as opposed to the levity and fluid nature of everyday conversational exchanges. A major problem with a binary opposition between the institutional and the everyday or ordinary is that we are assumed to have a clear understanding of what ordinary language or conversation is (Wilson 1989).

We can examine institutional language from two interrelated perspectives: (a) to what extent it is situation- and setting-specific; and (b) to what extent it is style-specific (both linguistically and interactionally). A number of scholars in sociolinguistics and pragmatics have addressed these issues in their study

of the role of language in a wide range of institutional and professional domains (e.g., Alatis and Tucker 1979, Atkinson and Heritage 1984, Atkinson and Drew 1979, Boden and Zimmerman 1991, Coleman 1984, 1985, di Pietro 1982, Drew and Heritage 1992, Fisher and Todd 1983, 1986, Gunnarsson et al. 1997, Labov and Fanshel 1977, O'Barr 1982, Sarangi and Roberts 1999, Sarangi and Slembrouck 1996, Wheeler 1969).

A common interest in the study of institutional language, following Douglas (1986), rests on the assumption that because institutions are primarily organizers of information, a study of patterned institutional routines can tell us something about how institutions work. This is the case if we turn to institutional practices in record-keeping and to the routine nature of information exchange in, say, emergency helpline calls, courtroom cross-examinations, medical consultations where accurate and precise information is sought in a sequential manner, in order to aid institutional and professional action.

2. Situational Aspects of Institutional Language

Among others, Labov and Fanshel (1977: 6) suggest that institutional language is 'specialised by its situation.' Drew and Heritage (1992), on the other hand, argue that setting or situation is not a definitional criterion of institutional interaction. Rather than equate institutional language with institutional settings, they claim that 'interaction is institutional insofar as participants' institutional or professional identities are somehow made relevant to the work activities in which they are engaged.' Following Levinson's notion of activity type, this includes: (a) orientations to institutional tasks and functions; (b) restrictions on the kinds of contributions to the talk that are, or can be, made; and (c) distinctive features of interactional inferences (Drew and Heritage 1992: 25). It is, however, arguable that

239

in professional–client encounters, participants do not necessarily display explicit orientation to the institutional agenda, thus making it difficult for analysts to locate setting-specific or style-specific features.

3. Linguistic and Stylistic Features of Institutional Language

Traditionally, using genre analysis (Swales 1990, Bhatia 1993), institutional language has been examined as text-types with identifiable linguistic and stylistic features. According to Redish (1983), institutional language, mainly in its written form, has a *nominal style* consisting of: (a) overuse of nouns (rather than substituting pronouns); (b) nominalization (verbs transformed into nouns as in *Failure to follow these directions will result in disqualification of the applicant*); (c) preference for passive constructions; and (d) use of noun strings (e.g., *healthcare maintenance organization*; *host area crisis shelter production planning workbook*). At the sentence level, institutional language is characterized by parallel syntactic structures, and these are particularly salient in the repetitive and tautological expressions in legal texts. The occurrence of complex syntactic structures can be partially explained by the written bias in institutional discourse.

Jargon or special vocabulary (including abbreviations) is another distinct feature of institutional language (Hudson 1978). Various professional groups, such as doctors, social workers, psychotherapists, use terms like 'muscular dystrophy,' 'deficient parenthood,' 'dysfunctional relationship,' without every time explaining the meaning of these terms. The use of technical terminologies is, as far as the 'insiders' are concerned, justified in terms of precision and indexing of expert knowledge. In different professional and institutional settings, everyday words can also acquire technical meanings. This observation underscores the analytical difficulty in divorcing style from setting in any discussion of institutional discourse.

4. Clash of Frames and Recontextualization Processes in Institutional Discourse

The discursive practices that professional groups draw on can be summarized as follows (Goodwin 1994: 606): (a) coding, which transforms phenomena observed in a specific setting into the objects of knowledge that animate the discourse of a profession; (b) highlighting, which makes specific phenomena in a complex perceptual field salient by marking them in some fashion; and (c) producing and articulating material representations.

Generally speaking, these practices are rooted in a notion of context which emphasizes the figure–ground relation (Duranti and Goodwin 1992). At another level, the categorization and representation associated with institutional discourse are also a reflection of differences in knowledge structure between professionals and clients (Collins 1987). For Agar (1985), there are not only two distinctly different interpretative systems—'institutional frames' and 'clients' frames'—but there is also a lack of fit between these frames. On the occasion of competing definitions of the situation, it is the institutional definition which often prevails. In the healthcare setting, for example, the difference between what Mishler (1984) calls the 'voice of medicine' and the 'voice of lifeworld' becomes marked and it is the 'voice of medicine' which is consequential. Central to this asymmetry of knowledge is the notion of recontextualization. As Cicourel (1983: 236–7) observes, patients often code information within a particular semantic domain using a 'content-based abstraction strategy' (and in a narrative style which includes feelings and emotions). Professionals and institutions, on the other hand, tend to map clients' information into a different symbol system which 'employs formal language abstraction.' Lifeworld conditions are thus transformed into abstract categories and, by extension, legitimated.

A further aspect of recontextualization involves the transformation of spoken interaction to written records in various professional settings. Note that institutions rely heavily on written language, in particular, medical consultation, social work, police interrogation, courtroom trial, psychiatry, etc. In the police interrogation setting, Jönsson and Linell (1991) point out that the written report is marked by a clearly elaborated narrative structure and a legally relevant language. Recontextualization here involves changes from vagueness to precision; from relative incoherence to coherence and a clear chronology; from emotionality to an objectively identified sequence of events and actions. As Garfinkel (1967) asserts, in professional settings records serve specific functions and are targeted at specific readers: there are 'good organizational reasons for "bad" clinical records.'

5. Asymmetrical Interactional Routines in Institutional Settings

Beyond the threshold of linguistic and stylistic features, and the differential distribution and recontextualization of knowledge among clients and professionals, information exchange in institutional settings is characterized by an asymmetry which is realized through interactional dominance: forms of address, amount of talk, and distribution of conversational rights (turn-taking, question–answer sequences, patterns of interruption).

If we take the systematic organization of turn-taking in conversation (see *Conversation Analysis*) as the norm (Sacks et al. 1974), then turn-taking patterns in the courtroom (Atkinson and Drew

1979), in the classroom (Sinclair and Coulthard 1975), and in news interviews (Heritage and Greatbatch 1991) are distinctively different: 'It is notable that these settings all involve the production of "talk for an overhearing audience"' (Heritage and Greatbatch 1991: 96). In sum, audience participation is controlled through turn design.

Turns constituted in question–answer sequences have been identified as a distinct parameter of institutional discourse. It may be possible to rank different institutional settings by type or question–answer sequence. For instance, the question–answer sequence is at its extreme in any kind of interrogation situation (courtroom, police, customs, immigration, etc.). Cross-examinations in courtroom settings operate with a prespecified speech-exchange system where each turn is either a question or an answer (Atkinson and Drew 1979). Questions are formulated in order to constrain and influence what the witness can or cannot say in reply, and by analyzing such exchanges it can be shown that in most cases the witness is positioned or encouraged simply to confirm statements. In medical-consultation settings, doctors typically ask a string of questions prefaced by *and* in a procedural manner to seek information from patients in order to arrive at a diagnosis. West (1984) reports that in doctor–patient communication, 91 percent of questions are initiated by doctors and only 9 percent by patients (see *Doctor–Patient Language*). In news interviews, interviewers start with a prefatory statement which establishes the context for a subsequent question. Interviewees withhold their response until a question is posed.

Prevalence of question–answer sequences in certain distributive patterns is not the only form of interactional asymmetry in institutional discourse. The right to interrupt (followed by topic shifts) is another mode of control. Other interactional features which constitute institutionality and which index the asymmetrical nature of the interaction include the absence, for example in talk used in meetings, of response tokens and backchannel cues, such as *mm hm, yes, oh, really, did you* (Boden 1994).

6. Discourse Strategies and Sociopragmatic Parameters of Institutional Discourse

If we adopt a view of language as action, the felicity and sincerity conditions associated with speech acts can be linked to the fact that institutional members are invested with authority and legitimacy. As Bourdieu (1991) (see *Bourdieu, Pierre*; *Symbolic Power and Language*) rightly points out, to think about speech acts in purely linguistic terms is to undermine the authority bestowed upon language by factors external to it. In this respect, the stylistic (linguistic and interactional) features are tied up with discourse strategies both at the levels of situated encounters and broader sociopolitical structures.

With regard to situated unequal encounters, Thomas (1985) suggests that certain pragmatic features (see *Pragmatics and Sociolinguistics*) are characteristic of the speech of dominant participants, while they are systematically absent from that of the subordinate participants. She calls these strategies 'metapragmatic acts' (illocutionary force indicating devices [IFIDs]; metapragmatic comments; upshots and reformulations), which dominant participants use to make explicit reference to the intended pragmatic force of their own or their subordinates' utterances. Metapragmatic acts, in explicating the communicative intent, can potentially remove the possibility of negotiating interactional outcomes. In conversational (equal) discourse, within Brown and Levinson's (1987) model of face-work and politeness (see *Politeness*), IFIDs occur in what they call 'costly-to-Speaker situations.' By contrast, in unequal discourse IFIDs occur in 'costly-to-Addressee situations.' The subordinate participant (that is the witness or defendant in court-room settings) is often forced to make on-record statements (which may be costly to himself/herself) through a carefully designed question–answer sequence.

In situations of potential conflict, the dominant speaker counters the challenge by demonstrating the necessary felicity conditions (appeal to official position, institutional procedure; rights and authority attached to position of speaking, etc.). This links with roles, modes of speaking, and face-management in institutional contexts (cf. Goffman's (see *Goffman, Erving*) notion of 'footing' and 'participant structure' in relation to information exchange; Goffman 1981). Participants in institutional settings occupy different role categories and they signal movement between available role categories linguistically using 'contextualization cues' (Gumperz 1982).

As with Brown and Levinson's principles of politeness, the Gricean maxims of cooperation also apply differentially in institutional settings. For instance, the maxim of manner is often violated in institutional discourse (jargons, complex syntax, etc.). Maxims of quantity, quality, and relevance are generally contested to a point at which distorted communication and noncooperation can be said to be characteristic features of institutional discourse (Habermas 1984, Harris 1995, Sarangi and Slembrouck 1992, 1996).

7. Language, Ideology and the Institutional Order

The surface-level realizations of institutional discourse (both stylistic and interactional) need to be accounted for with reference to social constructionism (Berger and Luckmann 1967, Herzfeld 1992) and, more generally, in the context of social theoretical accounts of institutional order (Foucault 1971, 1979, Weber 1930, 1947). Weber, for instance, outlines the following principles underlying institutional

activities; habitualization; depersonalization; economic rationality; norms; rules and procedures; neutrality. This suggests a kind of rigor about institutional discourse; however, from a critical perspective, discourses are to be seen as social practices which are subject to change over time. Foucault's historical accounts of institutionalization of health and illness, normality and deviance, etc., make the point about the reconfiguration of institutional orders of discourse; see also the thesis about 'the colonization of the lifeworld' put forward by Habermas (1989), which raises the issue about the private–public distinction with regard to language use (Sarangi 1995).

At another level, institutional discourse is increasingly being conversationalized (in terms of simulation of equality and informality) as a means for maintaining strategically the power differential between social groups (Fairclough 1992). Using critical discourse analytic methods, we can detect how local discursive changes are mapped onto broader sociopolitical events and vice versa. Here Giddens' (1984) model of duality of 'structure' and 'structuration,' which goes beyond the juxtaposition of the micro and the macro, is extremely useful.

In sum, as we have seen, institutional language is not an object which can be readily categorized using linguistic and interactional markers. Even informal, conversational diversions become embedded in institutional discourse and go on to confirm the predominance of the institutional way of thinking and doing, despite the choice of code and style. One is tempted to ask the question: does the Plain English Campaign, with its call for simplifying institutional language, actually amount to less bureaucracy with less bureaucratic language? Or, does it act as a further strategy to make the bureaucratic machinery less transparent (despite intentions that are opposite to this)? While paying attention to discursive shifts within and across institutional and professional settings over a period of time, it is also important to aim to consolidate recent findings about the institutional dimension of discourse in general. There are three possible directions for future research. First, there is a need for an analytic distinction between institutional and professional modes of talk, which would complement the growing number of studies devoted to institutions/professions versus clients (Sarangi and Roberts 1999). Second, a reassessment of various methodological frameworks (genre analysis, conversation analysis, [critical] discourse analysis, and corpus analysis) is necessary in light of our understanding of what constitutes institutional discourse. Third, and more specifically in the context of research in pragmatics, the pragmatic theories of face, politeness, cooperation, and relevance need to move beyond the speaker-oriented dyadic models of interaction, and at the same time become grounded in broader sociocultural parameters (e.g., power, inequality) which impinge on the study of institutional discourse.

Literary Language

R. Carter

One of the most defining characteristics of literary language is the impossibility of defining it in any simple way. Accounts of literary language are closely bound up with definitions of the term literature itself; and literature is a term which has been and continues to be subject to constant semantic change and redefinition.

Williams (1976) in *Keywords* points to how before the nineteenth century the term literature was used in an inclusive sense to mean 'writing' in the broader definition of written texts such as diaries, essays, letters, or travelogues. (In fact, such meanings continue to the present time when we refer to the literature on dog breeding, or the literature of an academic subject, or travel literature.) Since the nineteenth century, literature (and with it literary language) has acquired a less inclusive, more specialized sense and has come to be associated with imaginative or fictional writing in the main genres of prose, poetry, and drama. Such a definition still has institutional authority insofar as it is sanctioned by universities, school examining boards, and the media establishment. It also carries a distinctly qualitative association with writers and literacy texts being

canonized as either major or minor. Within such a definition it is clearly problematic to say that literary language is the language found in literature.

1. Intrinsic and Extrinsic Definitions

Definitions of literary language have tended to be intrinsic rather than extrinsic definitions; that is, there has been a focus on the language itself rather than on the source of the definition or on the institutional or ideological context in which the definition is made. Intrinsic definitions have concentrated on the perceived distinctiveness of literary language.

2. Formalism: Foregrounding and De-automatization

The Russian and Czech formalists were among the first in this century to explore the distinctiveness of literary language stressing above all some of the ways in which literary language can be said to draw attention to itself. One of the formalists' main theories is that of 'de-automatization' or estrangement which accounts for the ways in which literary language is marked when set against the 'norms' of ordinary language use. The notion is explained by the Czech formalist Havránek who uses the term 'foregrounding' to cover the ways in which literary style deviates from a background of normal or automatized language:

> By *automatization* we thus mean such a use of the devices of language, in isolation or in combination with each other, as is useful for a certain expressive purpose, that is, such a use that the expression itself does not attract any attention: ... By *foregrounding*, on the other hand, we mean the use of the devices of the language in such a way that this use itself attracts attention and is perceived as uncommon, as deprived of automatization, as deautomatized ...
>
> (Havránek 1964)

In his classic paper, Mukařovský (1964) argues that poetic language aims at 'the maximum of foregrounding,' that is, 'the aesthetically intentional distortion of linguistic components.'

For Mukařovský, 'The distortion of the norm of the standard is ... of the very essence of poetry.'

Furthermore, Mukařovský extends Havránek's inference that foregrounded usages attract attention to themselves by arguing that this special, 'poetic' language does not communicate in a way which is comparable with the normative, standard language. In fact, its main function is to be self-referring and primarily to communicate about itself:

> In poetic language foregrounding achieves maximum intensity to the extent of pushing communication into the background as the objective of expression, and of being used for its own sake; it is not used in the services of communication, but in order to place in the foreground the act of expression, the act of speech itself.
>
> (Mukařovský 1964)

3. Deviation and Parallelism

According to the formalists two main instances of foregrounding are 'deviation' and 'parallelism.' Deviation occurs when particular rules of grammar or of semantics are broken, as in this example from a poem by Gerard Manley Hopkins:

> There lives the dearest freshness deep down things; And though the last lights off the black West went Oh morning, at the brown brink eastwards, springs—
> *(God's Grandeur)*

Good examples of 'parallelism' would include anything which involved repetition. This can range from lexical parallelism as in the following example:

> What is this life, if full of care,
> We have no time to stand and stare.
> No time to stand beneath the boughs
> And stare as long as sheep and cows.
> (W. H. Davies *Leisure*)

to a more complete parallelism in which whole structural units are marked by being placed in a relationship of congruent repetition. A striking example of this structural parallelism is found in the first and last stanzas of William Blake's *Tyger* (in which one key word is replaced):

> Tyger, Tyger, burning bright
> In the forests of the night;
> What immortal hand or eye,
> Could frame thy fearful symmetry?
>
> Tyger, Tyger, burning bright
> In the forests of the night;
> What immortal hand or eye
> Dare frame thy fearful symmetry?

4. Contexts of Reading

There are a number of problems with formalist definitions of literary language. First, norms are difficult to define which in turn makes deviation difficult to measure. Second, to equate deviation with literariness is to suggest that literary language cannot result from adherence to norms, which in certain literary periods was a prerequisite for the creation of patterns of literary language. It is to equate literariness in language only with maximally deviant forms. Third, a context of reading is displaced. What is defamiliarizing stylistically in 1922 may not have the same effects 30 years later when readers have acquired a different set of expectations. Fourth, the opposition of literary and 'normal' or 'ordinary' language or of 'poetic' and 'practical,' everyday language can be deconstructed by pointing out that deviation routinely occurs in discourses such as advertizing, jokes, and newspaper headlines which are not institutionally connected with 'literature.' The

main problem with this kind of definition is its focus on the text-immanent, self-referential properties of literary language which are not located within a broader context. H. G. Widdowson points to a possible direction for a more inclusive, extrinsically related definition:

> It was observed in the preceding chapter that although it is quite common to find deviant sentences in literary writing, deviance of this linguistic kind is not a defining feature of literature. What does seem crucial to the character of literature is that the language of a literary work should be fashioned into patterns over and above those required by the actual language system. Whether the components of these patterns are deviant or non-deviant or both is of secondary importance. What I want to suggest now is that the effect of this patterning is to create acts of communication which are self-contained units, independent of a social context and expressive of a reality other than that which is sanctioned by convention. In other words, I want to suggest that although literature need not be deviant as text it must of its nature be deviant as discourse.
>
> (H. G. Widdowson 1975: 47)

5. Speech Act Theories

Accounts of literary language which attempt more boldly to underscore the role of the reader interacting in a sociolinguistic context with the sender of a verbal message are generally termed 'speech act theories' of literary discourse. Speech acts are uses of language which, either directly or indirectly, commit the user or recipient to a particular 'action.'

A basic proposition is that in literature the kinds of conditions which normally attach to speech acts such as insulting, questioning and promising do not obtain. Instead we have quasi- or mimetic speech acts. Ohmann (1971) puts it:

> A literary work is a discourse whose sentences lack the illocutionary forces that would normally attach to them ... specifically, a literary work purportedly imitates (or reports) a series of speech acts, which in fact have no other existence ... Since the quasi-speech acts of literature are not carrying on the world's business—describing, urging, contracting, etc., the reader may well attend to them in a non-pragmatic way and thus allow them to realize their emotive potential ...

Thus, the literary speech act is typically a different kind of speech act—one which involves (on the part of the reader) a suspension of the normal pragmatic functions words may have in order for them to be regarded as in some way representing or displaying the actions they would normally perform. That is, a promise or warning or threat by a character in a novel or by a person in a poem cannot be taken as a literal speech act. No one expects it to have any real-world effect. The statement 'come live with me and be

my love' is the first line of a poem, not an invitation to the reader.

The notion of a displayed, nonpragmatic, fictional speech act certainly goes some way towards explaining why we do not read Blake's *Tyger* for information about a species of animal or Wordsworth's *Daffodils* because we are contemplating a career in horticulture. Or why we cannot be guilty of breach of promise when that promise is in a love poem rather than a love letter (see Widdowson 1975, 1992).

However, speech-act or contextualist theories of literary discourse suffer from an essentialist opposition between literary and nonliterary which careful consideration does not really bear out. Pratt (1977), for example, has convincingly demonstrated that nonfictional, nonpragmatic, mimetic, disinterested, playful speech acts routinely occur outside what is called literature. Hypothesizing, telling white lies, pretending, playing devil's advocate, imagining, fantasizing, relating jokes or anecdotes, even using illustrations to underscore a point in scholarly argument, are then, by Ohmann's definition, literary.

6. Literariness in Language

There are thus basic problems in attempting to define literary language in essentialist terms or in terms which presuppose literary and non-literary polarities. As a result some stylisticians (e.g., Carter and Nash 1990, Carter 1999) have preferred to talk of literariness *in* language rather than of literary language, seeing a phenomenon of literary language as a cline or continuum rather than as an exclusive yes/no category. Within such a notion of literariness in language, texts are seen as displaying different degrees of literariness according to a *range* of 'tests' such as: the density of polysemic effects; the displaced character of the interaction between author and reader; the extent of independence of the text from other media (such as pictures, diagrams); the kinds of re-registrations of words and phrases from one context to another; and the density of iconic or representational uses of language. The tests are applied to a variety of texts ranging from car instructional manuals (nonliterary) to a novel by Anthony Burgess (literary) but with several 'intermediate' categories such as advertizing copy, jokes, and travel writing. Carter (1999) relates these notions to creativity in spoken discourse.

It must be recognized, however, that notions of literariness in language are as much in the reader as notions of literary language. They are not therefore objectively verifiable or attestable because they depend for their recognition on the readers who read them. Readers are socially situated and will read according to different ideological positions. Much will also depend on how they have been taught to

read for literary language, in as much as literature is what gets taught as such—is the product of a certain kind of reading. In more than one sense therefore literary language is an institutional category and extrinsic definitions serve as validly as intrinsic or essentialist definitions. Literary language may therefore best be seen as a socially and historically variable term with differently positioned readers framing different answers to questions concerning an appropriate definition. A very clear summary of this position is in Fowler (1981).

> To treat literature as discourse is to see the text as mediating relationships between language-users; not only relationships of speech, but also of consciousness, ideology, role and class. The text ceases to be an object and becomes an action or process. This anti-formalist approach is pretty much at odds with received opinion in conventional literary aesthetics. Among my heresies, from this point of view, are a willingness for literary works to be kinetic; denial of their alleged formal autonomy; acceptance of the relevance of truth-values to literature. It is not my purpose in this paper to argue a collision of linguistics and aesthetics, however—as I said, my immediate object is methodological. Furthermore, I shall assert, without offering any formal justification, one other assumption implicit in my position—that is, that no plausible essentialist or intrinsic definition of literature has been or is likely to be devised. For my purpose, no such theory is necessary. What literature is can be stated empirically within the realm of sociolinguistic fact. It is an open set of texts, of great formal diversity, recognized by a culture as possessing certain institutional values and performing certain functions.
>
> (1981: 80–1)

Intrinsic analysis helps to point up these values and functions but will always be a necessary but insufficient condition for a definition of literary language. As stated earlier, literary language is not in any simple sense the language of literature.

Media Language and Communication

K. C. Schrøder

The study of media language has not always taken seriously the fact that media language is part of a communicative process. But although many analysts have tended to treat media texts as relatively isolated objects of analysis, they have not (particularly in the areas of news and advertising language) refrained from making strong claims both about the possible motives of the senders in media institutions, and about the potential (ideological) impact of media language upon audiences. More often than not, when media language has been related to its production circumstances in media organizations, or to the audiences to which it is addressed, the focus has been on such behavioral–sociological aspects as journalistic work routines and gate-keeping processes, or on the commercial or ideological effectiveness, rather than on the detailed verbal and visual signifying processes that characterize media messages at all stages from sender to receiver. The 1990s have witnessed a development towards a more holistic perspective on media language, especially with respect to the crucial role of audience reception processes for the potential social influence of the media in contemporary society.

This article deals first, with mass communication as a sociocultural phenomenon, conceptualizing a

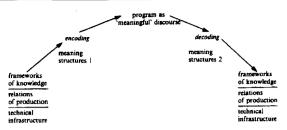
general framework within which media language can be meaningfully explored. Second, some of the most important approaches to the analysis of media language will be presented: critical linguistics and the analysis of news; semiotic approaches to advertising; discourse analysis and the broadcast media; and sociolinguistic perspectives on media voices. Finally, a concluding section will briefly outline developments towards an empirical pragmatics of media language.

Figure 1. (Reproduced with permission from Hall 1980).

1. The Mass Media as a Process of Communication

Mass communication can be briefly characterized as an institutionalized process encompassing the production, dissemination, reception, and interpretation of public sociocultural discourse (see *Discourse*). Historically, the modern media originate in the parallel emergence of the commercial and industrial bourgeoisie in the economic realm, and of the public sphere in the political realm. The dual role of the early printed press as a vehicle of both commercial and political interests has continued as social and technological development has made possible new types of media in the field of broadcasting. In recent years the emergence of a range of new electronic media and information technologies is heralding a partial convergence of mass-mediated and interpersonal forms of communication, as the mass media become more dialogic (or 'conversationalized' as Fairclough (1995) puts it) and new fora of interpersonal communication emerge on the Internet (Reardon and Rogers 1988, Slevin 2000; see *The Internet and Language*).

Since the 1980s the commercial and political aspects of the media have become increasingly intertwined, as all media are functioning under the necessity of capturing an audience. Consequently, even those (broadcasting) media whose 'public service' status might be thought to exempt them from commercial pressure have had commercialization forced upon them as they have to legitimate their existence by competing for listeners and viewers with commercial media organizations. Increasingly, therefore, the major media institutions address their audiences as both citizens and consumers, establishing a cultural and political forum constituted by a continuum of informative and entertaining genres.

It is only possible to understand the complex opportunities and constraints resulting from these communicative processes if one adopts a holistic perspective on media products. And since the media are above all disseminators of various types of sociocultural signs, it is necessary to approach them from a theoretical perspective that can explain mass communication as a signifying process. Such a broadly semiotic perspective is available in the so-called 'encoding/decoding' model of mass communication (Hall 1980) (see Fig. 1). What this model


implies is not that any study of a media genre or media coverage of real-world events must research, in addition to the textual aspects, the production and reception stages to which the text belongs. The model should serve to constantly remind analysts that in analyzing a text they are dealing not with a fixed structure of meaning, but with a volatile phenomenon resulting from the codes at the disposal of both the producers and the recipients of the text (see *Code, Sociolinguistic*). And crucially, these codes need not be identical; indeed, since the codes at the disposal of any individual consist of a unique assemblage of the meanings assimilated during that person's life history, the codes of producers and receivers are in principle nonidentical. In fact, some instances when analyses of news discourse accuse the news reports of 'distorting' reality may be explained by a difference between the codes of the analyst and the codes underlying the construction of the news text.

On the other hand, the occurrence of aberrant meanings that do not conform with the intended (so-called 'dominant') meanings should not be exaggerated; after all, people do belong to interpretive communities (constituted by such factors as class, race, gender, age, profession, location, etc.), in which meanings are shared to a large extent (see Schrøder 1994). Therefore, a purely textual analysis can still be justified in generalizing about the meaning structures found, as long as these generalizations are either offered cautiously as potential meanings, or made on behalf of a specific interpretive community whose sign universe makes these meanings plausible.

It has long been conventional wisdom within linguistics that the social context of a type of discourse heavily affects the specific features of that discourse, so as to enable linguists to characterize different variants of use, or registers. 'Media language' is much too diverse in terms of genres to make such a characterization possible, and the same holds for the language of individual media. One should not expect this article to deliver sweeping generalizations about 'the language of television,' or 'newspaper language,' although a skeletal characterization of advertising and some news genres will be attempted.

247

However, some researchers have attempted to generalize about the communicative mode of a medium, though not on the basis of its specific linguistic features. Thus Fiske and Hartley (1978: chap. 6) have defined national television as a 'bardic' medium with the communicative features usually associated with the bards of early European history: oral, dramatic, ephemeral, and communal, as opposed to the literate, linear, permanent, individual mode of print media. Arguing that these modes may correspond to Bernstein's restricted and elaborated codes (of working-class and middle-class language, respectively), they propose that television, with its broader appeal, is inherently more popular and democratic than print media.

2. Approaches to the Study of Media Language

2.1 Critical Linguistics and the Analysis of News

One of the most influential traditions in media language research since the late 1970s is that associated with the work of Roger Fowler, Bob Hodge, Gunther Kress, and Tony Trew (Fowler et al. 1979). Previous studies of the language of newspaper reporting (Crystal and Davy 1969: chap. 7) had analyzed the graphic, syntactic and morphological dimensions of news reports from a purely descriptive surface-structure perspective, leaving out any consideration of semantic and ideological aspects. The work of 'critical linguistics' faced head-on the issue of ideological transmission of social reality through the specific linguistic choices encountered in news reports (Fowler 1991).

The fundamental question which critical linguists are concerned with is the representation of social reality through language. As there can be no knowledge of social reality except through language, the way in which language represents the world to newspaper readers not only reflects, but effectively constructs the categories, frameworks, and values that people use to interpret their social environment. This is basically a Whorfian framework (see *Whorf, Benjamin Lee*) according to which the categories of language impose a mental/ideological grid on speakers' perception of reality. Moreover, since social reality in Western parliamentary democracies is penetrated by class conflict between dominant and dominated social groups, there will be a power dimension in all portrayals of that reality (see *Power and Language*).

Language and ideology are thus inseparable, and given the present relations of ownership and control of the press, newspapers are likely to present a version of social conflict that is ideologically biased in favor of the existing socioeconomic order and its concomitant relations of power and privilege. However, to conceive of news reports as ideological also implies that their partisan accounts of events appear as natural, unquestionable truth, 'the way things are.' It is the task of critical linguistic analysis to unmask the seemingly objective news accounts, to demystify the obscurations and distortions that would pass unnoticed without such analysis. The underlying epistemological project of critical linguistics is thus concerned with the political enlightenment of citizens whose confidence in the truthfulness of the news makes them accept a version of social reality that is not in their best interest. The underlying assumption, though never stated bluntly, is that if informed truthfully about social reality, people will take action in order to create a social order based on a more genuine freedom and equality.

The analytical toolbox which critical linguistics brings to the task of demystifying textual ideology is conceptualized within the framework of Halliday's functional grammar, and operates almost exclusively on the syntactic and lexical levels of textual organization. It is usually presented in the form of a checklist, describing a range of linguistic dimensions in which the choice of one form rather than another has ideological consequences:

(a) *transitivity features*, which belong to the ideational dimension and realize events, states, and processes by combing different types of participants (agent, affected, beneficiary, etc.) with different types of action signified by verbs. (As Fowler (1985) points out, the theoretical foundation of this analytical tool is akin to Fillmore's case grammar);

(b) *modality features*, which point to the interpersonal dimension of language, e.g., through naming conventions, personal pronouns, modal verbs, and adverbials;

(c) *transformations* like nominalization and passivization which, by condensing more complex structures, may obscure the real-world social processes they seemingly portray;

(d) *classification/lexicalization*, i.e., the way in which lexical choice orders reality in a specific manner, for instance, by activating powerful metaphorical meanings;

(e) *coherence*, which deals with the correspondence, or the lack of it, between surface cohesion and semantic, or logical, coherence.

In the following one of the classic analytical examples of critical linguistics will be presented in order to demonstrate how this tradition literally reads off the ideological significance from the linguistic choices and processes in a text (Trew 1979):

Before Zimbabwean independence a violent clash in then Southern Rhodesia between black demonstrators and

white police was reported in the following manner by the English newspaper *The Times:*

> RIOTING BLACKS SHOT DEAD BY POLICE
> AS ANC LEADERS MEET.
> *Eleven Africans were shot dead and 15 wounded when Rhodesian Police opened fire on a rioting crowd of about 2000.*

In the first part of an extensive analysis of the entire news report Trew notes how the choice of the passive form in the headline puts the syntactic agents of the killing, *police*, in a less focal position. In the next sentence the transformation process is carried one step further as the syntactic agent is deleted, or identified only weakly by implication through the temporal adverbial phrase *when police...*, etc. Second, looking at vocabulary, Trew notes how the choice of the word *riot* establishes a framework which legitimizes police action, because riot is by definition civil disorder requiring police action. Other analyses in this tradition emphasize the significance of metaphorical patterns established by lexical choice, as in a report which couches an antiapartheid demonstration in military terms (Kress 1985).

This type of analysis can be extremely rewarding as it scrutinizes the smallest detail of linguistic expression for its possible ideological implications. However, both in the analytical practice of its inventors and in that of their numerous followers, one finds exaggerated claims about the fatal consequences of agent deletion, passivization, nominalization, etc. First, although analysts often proffer assurance that a single linguistic transformation, like passive-deletion, does not have a one-to-one relationship to a specific ideological position, nevertheless in much analytical practice such individual instances of transformations are treated as if they did have direct ideological effects. Second, the analyses are generally based on erroneous assumptions about the 'non-recoverability' of transformed or deleted linguistic items; surely, on the basis of their overall knowledge of power in the world, their familiarity with yesterday's news reports, and their communicative competence, the average newsreaders will usually have no difficulty reconstructing who did what to whom. And, finally, the fact itself that war metaphors are used in the description of social conflict in no way predetermines whose side you are on. Interestingly, an empirical study of readers' understandings of newspaper articles previously analyzed by Trew found that the ideology of the articles did not determine the readers' view of the event reported, which depended on their life histories as much as on an ideological effect attributable to the news language (Sigman and Fry 1985).

By way of conclusion, then, 'critical linguistic' analyses of a news text are usually based on an *a*

priori oppositional ideological position to that from which the report is written, and the linguistic insights are used as weapons in an ongoing ideological struggle. In this sense, the analyst himself appears to speak from a position beyond ideology, for instance as he concludes that a news text just analyzed:

> is so far from the truth that only a powerful grip on the press and information and the diligence of the media in resolving the flood of anomalies which they report are adequate to preserve the pretence that the press is truthful.
>
> (Trew 1979: 106)

In some ways Fairclough's (1995, 2000) 'Critical Discourse Analysis' may be seen as a less dogmatic inheritor to the 'critical linguistics' approach, as it tries to cross-fertilize linguistic and sociological insights for the analysis of media discourse.

2.2 Semiotic Approaches to Advertising

The linguistic study of advertising has been motivated by concerns similar to those of critical linguistics described in the preceding section. Accordingly, the critical arsenal of advertising analysis has been shared with critical linguistics as far as the analysis of the verbal elements of advertising is concerned. However, because of its reliance on a combination of verbal and visual components, advertising has posed a particular challenge for textual analysis, which could clearly not afford to ignore the crucial visual/photographic dimension of advertisements. This challenge has been met by adopting the analytical framework developed in general semiotics.

Advertising serves a social function which is intimately connected to the foundation of the capitalist socioeconomic order: its job is to assist manufacturers in recovering profitably and as quickly as possible the capital outlay invested in production. It addresses people in their capacity as consumers, trying to catch their attention in order to motivate them to buy the commodities produced by the manufacturer. This function can be fulfilled in several ways, for instance, by providing factual information to consumers about the merits of a given product. However, for decades manufacturers have had to compete in a market characterized by the near-identity of products within product groups (detergents, cigarettes). It has therefore been necessary to develop advertising strategies which add to the material use-value of a product—or substitute for the material use-value—a symbolic or social use-value which is presented as the main attraction to consumers.

It is these 'suggestive' or 'persuasive' (as opposed to informative) strategies that have been the main target of advertising analysis, as they try to seduce

consumers into irrational social behavior. It has thus been demonstrated how advertisements exploit rhetorical strategies in order to present social prestige, sexual success, or family happiness as their unique selling proposition, deluding consumers into attempting to solve the problems emanating from social or psychological tensions by the acquisition of symbol-laden products. Such irrational consumer behavior lies at the heart of a major social malady: 'consumerism,' and it has been the purpose of hundreds of books about advertising to cure this widespread disease by unmasking the pleasant and fascinating verbal and visual surface of advertisements in order to penetrate into the underlying ideological manipulation. The dual aim of these studies has been to protect consumers by (a) provoking legislative intervention that could purify advertising of its manipulative devices and transform advertising into sober information, and (b) educating consumers about the pernicious strategies employed by advertising, so as to equip them with an immunity shield with which to resist the barrage of persuasive messages.

The principal concepts developed to handle the visual aspects of advertisements come from two sources: Roland Barthes's operationalization of the concepts of denotation and connotation for the analysis of photographs (Barthes 1964), and the adoption by many analysts of Peirce's concepts of iconic, indexical, and symbolic signs (Fiske 1990: chap. 3, Vestergaard and Schrøder 1985: chap 2).

Barthes finds it necessary to distinguish between two orders of meaning in a photograph: the 'denotative' level, which carries the innocent, factual meanings available to any observer irrespective of cultural or social background, and the 'connotative' level which carries the visual meanings that a specific culture assigns to the denotative message. Thus Barthes's original example presents an advertisement which denotatively pictures a string shopping bag with a number of items: onions, a green pepper, a can of tomato sauce, and two packets of pasta; the colors are yellow and green on a red background. In a French context this visual message acquires the cultural meaning (connotation) of 'Italianicity,' and as a selling proposition the advertisement offers not just a number of unrelated products, but the whole atmosphere associated with Italian cuisine. In similar fashion other advertisements may offer connotations like sexuality, family happiness, etc. in addition to the material use-value of the product. However, the fact that these connotations are grafted on to the underlying denotations, because carried by the same visual forms, may make them appear as equally naturally given and thus conceal from the consumer the fact that they are really ideological constructs. Consequently, message senders may use connotation to convey taken-for-granted meanings that are shared within a culture, without making these meanings explicitly available for critical scrutiny.

Before leaving the concepts of denotation and connotation it should be mentioned that although the distinction is extremely useful for analytical purposes its theoretical status within semiotics is highly questionable (Eco 1968).

The analytical terms borrowed from Peircean semiotics have to do with the relation between signs and their real-world referents: an 'icon' is a sign that is related to its referent through similarity (a photograph is an iconic sign of the phenomenon it represents, as is also a map); an 'index' is a sign which signifies by existential or physical connection with its object (smoke is an index of fire); and a 'symbol' is a sign whose connection with its object is purely a matter of convention (words and numbers are thus symbols).

All advertisements which have a pictorial element rely on the iconic relationship to real-world objects. This means that such advertisements lead themselves to analysis according to the denotation/connotation dimensions just described. In an extended sense, it is also an iconic relationship that is at work when advertisements employ visual metaphors: it is thus the visual similarity between a lipstick and the male sexual organ that leads some analysts to suggest that the lipstick may act as a phallic metaphor which may allegedly have subconscious effects on the female consumer. Similarly, verbal metaphors, in replacing one word by another which resembles it in meaning, rely on an iconic relationship between meanings; the classic advertising slogan *Put a tiger in your tank* exploits the iconic relationship by equating the (strength of the) tiger with (that of) ESSO gasoline.

In advertisements the indexical relationship appears in the way the product advertised is made visually contiguous to something else (for instance, a lifestyle) which is generally considered to carry favorable connotations. If the advertisement is successful, these connotations will then rub off on the product, although the juxtaposition may be quite arbitrary. The indexical relation may also occur in the form of a metonymic sign, in which a part is made to stand for the whole. For example, in a series of Rothmans cigarette advertisements a whole type of man was metonymically represented by a hairy, tanned hand in an aeroplane cockpit, signifying a masculinity associated with wealth, power, and control.

As is the case with connotations, indexes and metonyms may carry powerful ideological implications because they may seem to be naturally connected to that for which they stand. Their arbitrariness is easily ignored, so that they receive the status of unquestionable truths. This can also be

misleading in news reports where the necessarily partial account of real-world events directs one's perception of the whole of those events in specific directions. Thus a metonymic photograph of a single violent incident may convey a wrong impression of a demonstration that was otherwise peaceful and orderly. As this last example indicates, the semiotic framework may also be usefully employed in the analysis of news (Fiske and Hartley 1978: chaps. 6, 8, Hartley 1982).

So far, no mention has been made of the different types of implicit meaning: entailment, presupposition, and expectation. Although their occurrence is by no means restricted to advertising, their frequency of occurrence in this genre makes them into particularly useful analytical categories here. What they have in common is that something more is implied than is actually said. Where they differ is with respect to the origin of their implied meaning: with entailment and presupposition the implicit meaning is textually located, 'between the lines' so to speak. With expectation the implicit assumption arises from the situational context in which the utterance occurs. Advertisements will often use implicit meanings as a device to bring out of focus controversial meanings likely to enhance the advertisement's appeal to the consumer.

Entailment is what one can logically conclude from a statement. Thus when an advertisement promises that after a Pears Foam Bath *the world will seem a nicer place*, it is entailed that the world is usually not such a nice place—something the advertisement would never wish to declare straightforwardly.

Presupposition is what necessarily has to be the case for an utterance to be meaningful at all. Thus, when an ad. headline asks *Which of these continental quilt patterns will suit your bedroom best?* it presupposes both that *all these continental quilt patterns will suit your bedroom* and that *one of these continental quilt patterns will suit your bedroom better than the others*—so it is definitely worth the consumer's while to take a closer look at those quilts!

Expectation builds on the good-reason principle. Whenever something is said, it is assumed that there must have been some reason for saying it. The reason can be that what is said is not always the case, that the addressee would not have been aware of certain facts unless they were pointed out to him/her, and so on. One type of expectation consists of a sentence containing a negative word and an adjective in the comparative: *Beauty wise, value wise, you can't buy better than Rimmel* expects *Rimmel is the best you can buy*, although it actually asserts only *Rimmel is as good as anything else you can buy*. Whenever a negation is used to claim that the product is free of some undesirable characteristic, such a claim makes sense only because the rules of expectation permit us to deduce that competing products do have these characteristics—otherwise why bother to say it at all? Thus to say of a moisturizing cream that *it's not greasy or sticky* raises the expectation that *Other moisturizing creams are greasy and sticky*. While this type of expectation may be relatively harmless to the experienced consumer, others may be more pernicious in their ideological implication. Thus when an advertisement for two new types of canned Chinese food assures prospective buyers that *Here are two orientals you'll want to invite to dinner again and again*, it carries the expectation that, normally, Orientals are not welcome at your table and, by treating this prejudiced attitude as the most natural thing, the advertisement helps to legitimate it.

As the examples show expectation is an inferential process which may be theoretically accounted for in terms of Grice's Cooperative Principle (see *Cooperative Principle*) and Conversational Maxims (see *Conversational Maxims*).

Any observer will testify to the fact that advertisements vary immensely in form. However, they all have to accomplish certain communicative tasks for the advertisers; this makes it possible to suggest that in spite of their formal heterogeneity, ads generally follow the so-called 'AIDA' structure: an advertisement must (a) attract *Attention*, (b) arouse *Interest*, (c) stimulate *Desire*, and (d) get *Action*. In order to accomplish these tasks, advertisements tend to use specific communicative and linguistic strategies. Thus, in order to attract attention and interest, they will typically present visually fascinating material accompanied by speech acts of the *claim* or *promise* types, supported by such rhetorical devices as puns, metaphors, parallelisms, rhyme, alliteration, etc. The stimulation of desire will often be done through informational language in the main text (the so-called '*body copy*'), sometimes supported by celebrity and/or expert statements, appeals to science, and so on. Finally, in order to get action advertisements will usually refrain from flat imperatives urging the consumer to *buy*; they tend instead to rely on a range of indirect invitations to *try, ask for*, or *discover* the product (for a more detailed account for such linguistic strategies, see Vestergaard and Schrøder 1985: chap. 3).

In recent years, more and more scholars have adopted an increasingly skeptical attitude to the supposed effectivity of advertising's rhetorical tricks. It has long been recognized that people distrust the overt claims made by advertising. Possibly, after years of exposure to print and TV advertisements, people are far beyond merely distrusting exaggerated claims. As reception studies have shown, they may well have developed from gullible victims into resourceful skeptics, with an awareness that ads belong to the realm of illusion and should be approached with a mixture of caution and playfulness (O'Donohoe 1997, Schrøder 1997). Aesthetic

251

and rhetorical changes in the advertisements themselves since the 1980s, especially the meta- and intertextual dimensions in advertisements addressing the young generation, may be interpreted as indicators of a communicative change in progress taking advertising beyond the role of the dreaded hidden persuader (Nava and Nava 1990, Cook 1993, Myers 1994).

2.3 Discourse Analysis and the Broadcast Media

Discourse analysis (see *Discourse*) is here used in a wide sense, which includes all approaches to media language that focus on the textual levels above the sentence. The 'applied' perspective on theoretical positions adopted in this article makes it unnecessary to distinguish between the slightly different emphases of the two main traditions that have contributed significantly to the analysis of the larger units of media discourse: on the one hand, coming out of linguistics, discourse analysis proper, which is concerned with the extension of the structural models of linguistic description to the levels beyond the sentence; on the other hand, conversation analysis, coming out of microsociological ethnomethodology, which focuses on speakers' routine accomplishment of everyday verbal interaction (see *Conversation Analysis*).

Both approaches build on a pragmatic speech act perspective (see *Pragmatics and Sociolinguistics*) that makes it natural for them to address the complex interrelation of textual and contextual factors, and not to overemphasize linguistic structure itself. The analysis of news reports within this perspective thus tries to take into consideration the organized conventional knowledge (called 'frames' or 'scripts') (see *Artificial Languages*) which news readers/listeners/viewers bring to the interpretation of the news message. Such frames are held, for instance, to enable recipients to disambiguate headlines, and to interpret temporal adverbial clauses as causal indicators (e.g., *. . . when police opened fire . . .*). While acknowledging the analytical potency of the categories used by 'critical linguistics' (see Sect. 2.1), discourse analysts tend not to jump to conclusions about ideological impact. In this sense discourse analysis is descriptive rather than evaluative, and the question of audience response is referred to empirical investigation (van Dijk 1983).

One thing that discourse analysts have explored is the possibility of developing a narrative grammar for different textual genres. Van Dijk (1983) proposed the model of the macrostructure of news discourse shown in Fig. 2. These categories are said to be 'prototypical' of news discourse, i.e., they need not all be present in all news reports. It will be seen that this structural model has been extended by analogy from the well-known constituent models of structural-descriptive sentence grammar and transformational

1. Summary/introduction
1.1 Headlines (with super-, main-, and sub-headlines, and captions)
1.2 Lead

      2.1.4.1 Context
      2.1.4.2 Background
2.2 Consequences/reactions
   2.2.1 Events
   2.2.2 Speech acts

3. Comments
3.1 Expectations
3.2 Evaluation

Figure 2. The macrostructure of news discourse.

grammar. It may even be represented in a hierarchical tree diagram, and the various categories may be subjected to transformations before they appear in actual news performance in a different order, or with empty slots after the deletion of optional elements. On their passage from underlying structure to actual news text, the narrative categories must be embedded within a 'presentational structure,' consisting of layout features, photographs, and illustrations, etc.

In order for such models to be applicable to broadcast news they have to be supplemented by a consideration of the presentational variables specific to these media, taking into account two communicative axes: that between the various participants in the newsroom (anchorman, co-anchors, interviewer and interviewee, on-location reporters, news footage voice-over, etc.), and that between the aggregate news broadcast and the audience.

As regards the latter, the fact that broadcast news is a type of simulated interaction makes necessary the constant insertion into the news text proper of a range of meta-discursive devices which guide the audience from one element to another (*Our next story deals with . . .*) or which identify the status of whoever happens to be speaking (the tags under interviewees' faces; presentations like *We have an eyewitness report from . . .*). Television news obviously requires a detailed semiotic attention to the visual aspects and their relation to the verbal report (Hartley 1982).

Not surprisingly, discourse analysts have devoted a great deal of interest to the most interactive genre of broadcast news: the news interview (Heritage 1985, Greatbatch 1988). In such studies one looks in vain for an analysis of the possible ideological meanings of utterances; all attention is focused on the interactive dynamics of the interview exchanges as their turntaking patterns are explored through a comparison with those of ordinary everyday

conversation in order to illuminate the specific constraints and options that govern the production of such interviews.

Noting that news interviews deviate systematically from ordinary conversation in replacing the latter's question–answer–receipt pattern (*A: How's yer foot?—B: Oh it's healing beautifully—A: Good*) with a question–answer–question sequence, Heritage (1985) explains this difference by the fact that news interviews are produced primarily for an overhearing audience: by avoiding the evaluation inherent in the third-turn 'receipt response' characteristic of normal conversation, the interviewer declines the role of answer recipient while maintaining the role of answer elicitor. The importance of the overhearing audience also manifests itself in the frequent occurrence of so-called 'formulating' utterances (*Interviewer: So you're suggesting that ...*) in which an interviewer may sum up an interviewee's answer, or make explicit potentially controversial implications of the answer. These 'formulations,' performed on behalf of the viewers, serve to maintain the news audience (rather than the interviewer) as primary recipients. In addition, formulations may serve an important function within the institutional framework of public-service broadcasting, which requires its employees to maintain impartiality and balance in the coverage of controversial matters: with a formulation an interviewer can bring attention to a sensitive aspect while ostensibly merely rephrasing what the interviewee has already said.

A completely different type of TV interaction for an overhearing audience is analyzed by Crow (1986), who explores the conversational pragmatics of *Good Sex*, a New York-based phone-in advisory program, a genre which falls between private interpersonal talk and talk explicitly designed for an overhearing audience. The hierarchical structure shown in Fig. 3 (based on Crow 1986) is proposed for this type of program. As with news interview studies, the sole emphasis here is on the conversational dynamics and structural pattern of the televised telephone talk, on the 'rules' which make this type of conversation work and the strategies for handling possible 'breakdowns,' and any interest in the program content as such or the appropriateness of the advice is expressly disclaimed.

Attempts have also been made within discourse analysis to analyze broadcast monologue. Montgomery (1986) takes up the challenge of analyzing disc jockey (DJ) talk, a type of extempore monologue between records whose lack of turntaking sequences makes it hard to isolate the structural units of which it consists. Whereas the monologue of radio news is a third-person genre, DJ talk operates along the axis between first and second person, foregrounding the relationship to the audience. Thus, the DJ of Montogomery's study summons his unknown, invisible listeners by name, region, occupation, star sign, etc. He thereby establishes a direct interpersonal relation to one individual or segment of the audience, for the moment relegating the rest of the audience to the status of overhearing audience, only to shift the boundary between addressee and overhearers with his next summons. He thus potentially involves the entire audience in the I–you relationship. Also, as he simulates a dialogue with his listeners the DJ employs the first utterance of an adjacency pair (see *Conversation Analysis*) such as greetings and question–answer pairs, without any sign of awkwardness that the second is never forthcoming. By thus constantly making his listeners aware of other (invisible) members of the audience and their own potential participation, the DJ seeks to implicate each listener in an imagined community constructed from colloquial monologue. Scannel (1991) presents a diverse range of studies on different types of linguistic interaction encountered in the broadcast media. For recent examples of media discourse analysis based on discussive psychology, see Billig 1995, Potter 1996.

2.4 Sociolinguistic Perspectives on Media Voices

One of the ways in which speech and writing differ from each other lies in the signifier's capacity to function as a social indicator: the material form of speech inevitably acts as a signifier for such categories as gender, class, ethnicity, age, etc., while written language, and in particular print language, is more or less neutral with respect to these social categories of the speaker.

For this reason, print media have historically been more inclined to grant equal access to individuals

Episode	Call			
Sections	Opening	Problem Formulation	Advice	Closing
Sequences (consisting of 'acts')	Greetings Identification (Compliment)	Pre-question Question	Answer Formulation	Pre-closing Thanking Update request Terminal exchange

Figure 3. Structure of phone-in TV dialogue (based on Crow 1986).

who did not belong to the 'right' class, gender, race, etc. It has been shown how the selection of the 'right' accent for BBC radio speakers has been related to the wider social and sociolinguistic context in the UK since the 1920s, resulting in the exclusive recruitment until the 1960s of speakers of Received Pronunciation (RP), a nonregional prestige accent. Leitner (1983) thus finds that it was the unspoken assumption for decades, although never proven empirically, that RP was better understood in the UK than any other accent, and that it was the only appropriate accent for radio. This language policy was in line with the paternalist educational aim of public-service broadcasting in the UK, as well as in many other European countries, where the broadcasting intelligentsia felt a need to establish daily in the minds of the public what correct speech should be. From the 1960s, modified versions of RP and some regional accents gradually became acceptable, as social developments towards greater equality and less formality called for a more symmetrical relationship between broadcasters and audiences. The emergence of nonstandard accents in broadcasting news is also related to the increased division of labor in the newsroom and to the competition between channels which have put a premium on immediacy and authenticity, promoting a more popular idiom in pronunciation as well as in vocabulary and syntax (Leitner 1983).

Research on gender and media has looked specifically at the way the female voice has been stigmatized in media discourse: the low social prestige and authority possessed by women has been transferred to the properties of their voice, which has consequently been deemed unsuitable for broadcasting at least until around 1980. Thus a BBC Announcer's Handbook in 1959 stated that 'women's delivery is lacking the authority needed for a convincing newscast' (quoted in Key 1975: 72); in the USA, a TV network president declared in the early 1970s that 'audiences are less prepared to accept news from a woman's voice than from a man's' (quoted in Eakins and Eakins 1978: 106). Similarly, female voices have been used quite rarely for the authoritative-expert voice-overs in TV commercials (Marecek et al. 1975: 160). However, as increasing numbers of women reach the upper echelons of the social hierarchy, the social value attached to their speech (and hence their visibility/ audibility in broadcasting) is increasing proportionately.

3. Future Perspectives: Towards a Pragmatics of Media Language

Since the mid-1980s, growing numbers of scholars have begun to question with increasing intensity the validity of the claims made on the basis of textual analysis alone about the ideological impact of media messages on recipients. How valid, for instance, is the insight gained from an elaborate analysis of the metaphorical meaning of a reference in a *Dynasty* episode to 'The Boston Tea Party,' if this soap opera's massive non-American audience decodes this expression as a reference to a hypothetical tea party in the immediate serial past (Schrøder 1988)? Or how could one have anticipated through textual analysis that in Madonna's rock video 'Papa don't preach' the teenage protagonist's decision that I'm keepin' my baby' is taken by white audiences to refer to her facing the prospect of teenage pregnancy, while black audiences take the word 'baby' to refer to the boyfriend her father wants her to give up (Brown and Schulze 1990)?

Such problems cannot just be done away with as if they merely arose from 'misunderstandings' of individual words. It has to be realized that linguistic meanings are not univalent units in an abstract language system as supposed in Saussurean theory, but polyvalent, as held by theorists like Peirce and Voloshinov. It is thus no coincidence that a change of theoretical perspective is emerging where the Peircean definition of the sign is perceived to be more adequate for a science of the life of signs in society, because it accords a crucial role of those who use the signs: 'A sign (...) is something which stands *to somebody* for something in some respect or capacity. It *addresses somebody*, that is, creates in the mind of that person an equivalent sign (...)' (Peirce 1985: 5, emphasis added).

In other words, a Peircean perspective conceptualizes the analysis of media language not within a general, abstract linguistic system where meanings are fixed, and assumed to be mechanically transferred to recipients' minds, but in a communicative context where meanings are only potential until actualized by socially situated human beings (Jensen 1995).

What is being developed is a comprehensive social semiotic where verbal language is conceived in relation to all other socially constituted sign systems, treated as social practices (Halliday 1978). However, analysts differ in their assessment of the theoretical and methodological implications of such a revised perspective. Pateman, for instance, argues that textual analyses of connotations often have an extremely 'hazardous character, inviting the question "How do you know?"' (1983: 187). But as Pateman calls for a revised, more pragmatic perspective which takes into account the 'active comprehension of texts and images,' he nevertheless declines to add an empirical dimension to connotation analysis, fearing that this will 'place the locus of interpretation solely in the receiver, which is just as much an error as to place it wholly in the text' (1983: 200). Others, however, think that the empirical inclusion of senders and receivers is imperative for the analytical credibility of media language research (Deacon et al. 1999, Gavin 1998).

One consequence of the adoption of a holistic social-semiotic perspective on media language will be that in addition to focusing the analytical spotlight on media language itself the analyst must also explore the discursive practices through which media texts are encoded and decoded. This requires the analyst to supplement traditional forms of critical analysis of the media text with ethnography-inspired fieldwork, which then produces new textual objects of analysis in the shape of transcripts of qualitative interviews with media producers and audience members about the meaning processes they engage in (Lindlof 1995). Clearly this new research agenda is no less imbued with theoretical and methodological hazards than that of traditional media language analysis, which may explain the reluctance of media discourse analysts to for instance embark on the kind of audience fieldwork whose necessity they readily acknowledge (Fairclough 1995).

Whether one is interpreting the language of a media text or audience discourse about such a text, it should be remembered that any code or language has embedded within it a vast number of separate codes or languages that are molded by race, class, region, gender, etc.:

> At any given moment of its historical existence language is heteroglot from top to bottom: it represents the coexistence of socio-ideological contradictions between the present and the past, between different epochs of the past, between different socio-ideological groups in the present, between tendencies, schools, circles and so forth, all given a bodily form. These 'languages' of heteroglossia intersect each other in a variety of ways, forming new socially typifying 'languages.'
> (Bakhtin 1981: 291, quoted in Newcomb 1984: 39)

In other words, in a heteroglot society meaning is multiply variable, and any understanding of a text produced by another human being, or social institution, is a translation from that speaker's idiolect into one's own. No textual analysis is exempt from the fact that every decoding is always another encoding.

Medical Language

J. Maclean and J. C. Maher

By 'medical language' the lay person usually means the technical terms of medicine. In linguistics, the term medical language is used in a wider sense to refer to the variety of language used by medical personnel in communication with each other and with patients. It therefore includes not only the register of medical terminology, but also the preferred choices of lexis and syntax, typical discourse structures (case histories, operation notes, research articles, etc.), and any other features which are distinctive conventions of the language used in medical contexts.

1. Medical Terminology

Medical terminology is primarily a nomenclature of labeling and description. In this respect it differs from, say, law, where the function of the terminology is to construct through definition a system of concepts. Anatomical parts, physiological processes, symptoms and signs of disease, etc. once identified are given names, which often are descriptive labels. For example, the 'stapes' (Latin *stapes* 'stirrup') is a stirrup-shaped bone in the ear; the 'sublingual nerve' (Latin *sub* 'under,' *lingua* 'tongue') is the nerve under the tongue; 'hematuria' (Greek *hemat-*'blood,' *ur-* 'urine') is blood in the urine. The great majority of medical terms are nouns.

Registers of medical terminology are developed as new terms are introduced for new findings and concepts. This process is most evident when one culture encounters and absorbs the science of another culture so quickly that terms have to be borrowed from the other language. Thus Latin incorporated much terminology from Greek, borrowed at the time of the Roman conquest of Greece, where the Romans found a science of medicine far in advance of their own. Likewise, Japanese borrowed most of its terms for the internal organs from Chinese in the sixth century. More recently, Navajo (*Navajo*), which has a detailed vocabulary for the skeletal system but almost none for the circulatory and nervous systems, has had to borrow medical terminology extensively from English.

From the fifth to the seventeenth century, Latin was the European lingua franca for medicine as for other fields of knowledge. To the Greek-derived terms already predominant in early medical Latin (e.g., *asthma*) the anatomists added terms from lay Latin (e.g., *pollux*). As the science developed, new terms were created in all fields of medicine, either making direct use of Latin and Greek words (e.g., Latin *scapula humeri*; Greek *anorexia*) or creating new words from Latin and Greek roots (e.g., 'cardiopulmonary').

In the second half of the twentieth century English emerged as the predominant lingua franca in medicine. As was the case in medical Latin, in English the register of medical terms contains lay terms (e.g., the nouns 'heart,' 'liver,' 'nerve'). These exist alongside terms of Latin and Greek origin (e.g., the adjectives 'cardiac,' 'hepatic,' and 'renal'). English is used for some new terms, particularly for the naming of syndromes (e.g., 'acquired immunodeficiency syndrome'), but Latin and Greek roots continue to be used for new terms in the biological sciences and even in clinical medicine (e.g., *status anginosus*). Terms formed from Latin and Greek words or roots predominate in most European languages (e.g., English 'hepaticotomy'; German *Hepatikotomie*; Spanish *epaticotomia*). Etymological studies indicate that words derived from Greek or Latin account for as much as 90 percent of the medical terminology in international use today.

1.1 Morphology of English Terms Derived from Latin and Greek

Words taken directly from Latin and Greek generally retain their Latin and Greek plural forms: e.g., 'conjuctiva, PL conjuctivae'; 'bacillus, PL bacilli'; 'metastasis, PL metastases'; 'arthritis, PL arthritides'; 'dendron, PL dendra.'

Many Latin and Greek derived medical terms consist of two roots joined with the so-called combining -*o*-, often with an affix. Combinations are made with two noun roots (e.g., 'musculoskeletal') or with an adjective and a noun root (e.g., 'microcephaly').

Prefixes can be Greek and Latin prefixes (e.g., 'anemia, exophthalmos, diverticulitis') or Greek and Latin prepositions (e.g., 'hypokalemia,' 'hypertension,' 'diarrhea,' 'epigastric,' 'pericardium,' 'transurethral'). Suffixes include: '-itis' = inflammation (e.g., 'appendicitis'); '-osis' = abnormal condition, often an excessive quantity (e.g., 'erythrocytosis'); '-algia' = painful condition (e.g., 'neuralgia'); '-oma' = tumor (e.g., 'melanoma'); '-tomy' = cutting (e.g., 'tonsill-ectomy').

The last syllable of the original Latin or Greek root is sometimes dropped from the first of two combining forms (e.g., 'tenosynovitis' instead of 'tenontosynovitis'; 'hemochromatosis' instead of 'hematochromatosis'; 'volumetric' instead of 'volumometric'; 'pulmotor' instead of 'pulmonomotor'; 'contra-ception' instead of 'contraconception'; and even 'urinalysis' instead of 'urine analysis').

The formation of adjectives from nouns ending in '-ology' is different in American and British English. For example, American English has 'biologic,' 'pathologic,' and 'pharmacologic' compared with British English 'biological,' 'pathological,' and 'pharmacological.'

1.2 British English Spelling of Terms Derived from Latin and Greek

British English retains the spelling *ae* ('anaemia, aetiology,' etc.) and *oe* ('oedema, diarrhoea,' etc.), whereas American English has replaced both *ae* and *oe* with *e* ('anemia,' 'etiology,' 'edema,' 'diarrhea'). The anomalous form foetus (Latin *fetus*) found in many British English texts and dictionaries presumably results from overgeneralization of the British–American spelling contrast.

1.3 Eponyms

A characteristic feature of many compound medical terms is the inclusion of the name of the physician, surgeon, or medical scientist who first recognized, discovered, proposed, or invented the entity named by the term. Thus we have: 'Bell's palsy,' 'a Colles' fracture,' 'Coombs' test,' 'the Epstein-Barr virus,' 'Golgi cells,' 'Kaposi's sarcoma,' 'Koplik's spots,' 'Kussmaul breathing,' 'the Laurence-Moon-Beidl syndrome,' 'McBurney's point,' 'Parkinson's disease,' 'Romberg's sign,' 'Wernicke's encephalopathy,' 'Willett forceps,' and many more.

In a related set of terms, a condition typical of a person or a group retains that name whatever the context. Examples are: 'tennis elbow'; 'housemaid's knee'; 'farmer's lung'; 'Legionnaires' disease.'

Eponymic terms cause difficulties in alphabetical indices, partly because attribution may be made to different physicians, or variously to one worker or co-workers (as in 'Dorothy Reed cells,' also called 'Sternberg–Reed cells'). Terms including both names of one person (as in 'Dorothy Reed cells') are also a problem to place alphabetically. There is inconsistency in the use of 's: e.g., both 'the Babinski response' and 'Babinski's response' are found. Attempts are being made by some editorial bodies to replace some eponymic terms and to standardize others. In particular, some recommend dropping the 's in all eponymic terms.

1.4 Noun Compounding

Noun compounding is a common feature of medical terminology in some languages, the English equivalent being the use of nouns to modify a head noun. Examples are the Japanese *ketseki-gyoko-inshi*, equivalent to the English 'blood clotting factor,' and German *Antigen-Antikörper-Reaktion* and *Blutkörperchensenkungsgeschwindigkeit*, equivalent to the English 'antigen antibody reaction' and 'erythrocyte sedimentation rate.'

1.5 Metaphor in Medical Terminology

Medical terminology, being descriptive, makes much use of metaphor. Examples from food are: 'orange-peel skin,' 'café-au-lait spots,' 'a strawberry nevus,' 'a chocolate cyst'; from architecture: *lumen* (Latin

'threshold'), 'the abdominal wall,' 'the aortic arch'; and from clothing: *tunica intima* (Latin 'inner garment'), *sinus* (Latin 'fold containing a cavity'), 'glove-and-stocking sensory loss.' A 'capillary vessel' is a container like a hair (Latin *capillus* 'hair'). The shapes of the following lesions are clear from their names: 'stellar angioma,' 'spider nevus,' 'butterfly rash,' and 'splinter hemorrhage.'

2. International Medical Communication

English is now widely employed as a medium of instruction in medical schools in countries where it is a second or foreign language. It is the main medium for medical textbooks, journals, and abstracting indexes, and is by far the most used language in international medical meetings (Maher 1986).

The English used in medical education and research shares many characteristics with the English used in any academic scientific field. The lexis, apart from medical terminology, is typically 'subtechnical academic': it has been pointed out, for example, that physiological processes do not 'happen'; they 'occur.' Studies of the genre of the English language research report (Swales 1990) indicate the typical discourse moves and their linguistic exponents; the distribution and frequency of the passive voice; linguistic evidence of strategies of politeness and hedging in discussion; and the functions of verb tense choice in expressing authorial attitude when citing other work. Complex noun phrases have been noted in several studies to be a particularly striking feature of medical writing, especially complex premodification (e.g., 'the *in situ* saphenous vein bypass'; 'carbohydrate-stimulated high oxidative shunt enzyme tissue levels').

Medical writing is distinguished from other academic writing in the degree of control exercised by eminent medical editors and writers (Council of Biology Editors 1983, Huth 1987). The so-called Vancouver style format is now the recognized standard information structure for medical research reports. Authoritative lists or nomenclatures exist to encourage international consistency in the use of medical terminology. Standardized units of measurement are advocated. Advice is also given, perhaps with less success, on 'good medical style': i.e., avoiding pomposity, slang, cumbersome noun phrases like those quoted above, dangling participles, and overuse of the passive.

3. Medical Language in Hospitals

Communication networks and other procedural aspects of communication in hospitals have been much studied, but there are comparatively few studies of the language used in the communication of medical information.

Communication about patient care is standardized in the hospital record system in reports, forms, and charts, all with well-defined information structures.

Pathology reports and operation notes have been analyzed with respect to syntactic and grammatical features, but little has been written about the case report, which is the central report in hospital medicine. A case report is divided into sections on the presenting complaint, past history, investigations, diagnosis, management, and outcome, each section having typical linguistic exponents. For example, in the presenting complaint section there typically occur complex time and tense expressions, listing of symptoms, and standardized collocations (e.g., 'presented with,' 'complained of,' was admitted with'). The examination and investigation sections are typically in past time, in simple or coordinate sentences, presenting both negative and positive findings, and utilizing a different restricted set of collocations (e.g., 'on examination,' 'no abnormality was found,' 'microscopy revealed').

The medical language used in hospitals reflects the working environment with semitechnical words like 'trolley,' 'syringe,' and 'ward round'; verbs and verbal collocations denoting clinical actions, e.g., 'to pass a tube,' 'to insert a drain,' 'to withdraw a catheter,' 'to set up a line,' 'to scrub up'; certain prepositional collocations, e.g., 'on admission,' 'on discharge,' 'on auscultation,' 'on palpation'; 'at laparotomy,' 'at delivery,' 'at autopsy.' Abbreviations are common: e.g., 'A & E,' 'OPD,' and 'CCU' are the Accident and Emergency Department, the Outpatient Department, and the Coronary Care Unit. Abbreviations are extremely common in case notes, for symptoms (e.g., 'D & V' for diarrhea and vomiting), signs (e.g., 'JVP' for jugular venous pressure), investigations (e.g., 'LFTs' for liver function tests), diagnoses (e.g., 'ca. Br.' for bronchial carcinoma) and so on. Report forms of all kinds further encourage the use of abbreviations, which are transferred to speech: e.g., 'we had a DOA night' (i.e., dead-on-arrival); 'it might be an MI' (i.e., a myocardial infarction); 'her Alk. Phos. is raised' (i.e., alkaline phosphatase level); 'have you done the tprs yet, nurse?' (i.e., the temperature, pulse, and respiration rates). Form-filling is also the source of such expressions as 'she's got query appendicitis' and 'urine three plusses.'

Medical writers have commented, usually with disapproval, on the creation of verbs from nouns: e.g., 'laparotomize' from 'laparotomy,' 'diurese' from 'diuresis,' 'hemoptysize' from 'hemoptysis,' 'endoscope' from 'endoscopy.' They have also noted the 'sloppy' use of medical terminology in expressions like 'the diabetic leg' and 'a severe pathology.'

Nonstandard language is frequent. It is ephemeral, jocular, and sometimes macabre (e.g., *gorked out* 'comatose'; *GOK* 'God only knows'; *a crumbly* 'an old person'). It has been suggested that medical slang may relieve feelings of distress in the face of sickness and pain, and, together with the technical jargon,

may serve to reinforce the bonding of the members of the group.

4. Doctor–Patient Language

In hospitals in many parts of the world, notably Africa, the Middle East and the Indian subcontinent, different languages are used for speaking with patients and speaking with colleagues: the local language when speaking to patients and the official hospital lingua franca (usually English) for communicating with medical staff and for medical records.

However, even in an English-speaking environment, doctors use different varieties of English with patients and with colleagues. Medical terminology represents shared expert knowledge, and is not normally appropriate for communicating with patients. Thus, doctors speaking to patients are likely to say: e.g., 'thighbone' rather than 'femur'; 'whooping cough' rather than 'pertussis'; 'navel' rather than 'umbilicus'; 'bend' and 'straighten' rather than 'flex' and 'extend.' A few terms are specific to this variety of English (e.g., 'front passage' instead of 'vagina'; 'waterworks' instead of 'urinary system'; and 'motions' instead of 'feces'). These refer to body parts and functions for which other terms are either inappropriately medical or inappropriately vulgar. The difference between expert and lay knowledge leads to different meanings for some words: e.g., 'anxiety' and 'shock' have more stable and specific meanings in medical terminology than in the patient's language.

Register

W. Downes

'Register' describes variation in language according to use. It captures the intuition that there are functionally distinct varieties of language in such contexts of situation as sport, science, or advertising. Such variation contrasts with variation by user, or dialectal variation. Literary texts are often characterized by an allusiveness to nonliterary registers. This makes relevant the social meanings of the language alluded to, deploying its context into the text. Such 'reregistration' (Carter and Nash 1983: 129) is arguably central both to intertextuality (the interdependence of a text on all those that have gone before it) and the literariness of literary texts. The question remains open whether literature itself defines a register.

1. Register as Meaning Potential

Although register is sometimes used loosely in sociolinguistics, stylistics, and applied linguistics to label a 'way of speaking,' the term itself is particularly associated with the systemic–functional school of linguistics and with the functionalist stylistics associated with that school (for references see Birch 1989: 25–9, 139–45, Birch and O'Toole 1988: vi–ix, 1–11).

Thus, the notion finds its place within the linguistics of M. A. K. Halliday (see *Halliday, Michael Alexander Kirkwood*) and his associates and has undergone considerable development as a technical term. In its early use a situation type was claimed to determine uniquely frequencies of linguistic forms, producing, appropriately to the situation, a characteristic textual pattern of superficial lexical and grammatical items (see Halliday et al. 1964: 87–98). It is worth noting at the outset that register has always been a probabilistic entity and therefore is, like 'dialect,' vague in the absence of quantifiable situational parameters. It nevertheless remains an intuitively valuable analytic tool (see *Dialect and Dialectology*).

In *Language as Social Semiotic* (Halliday 1978) the concept of register has a role in a much more comprehensive sociological linguistics. The strength of this theory is that it connects text to the social system and the context of culture. A text is an interactive semantic process. It is interpreted as an instantiation of meanings, semantic choices from the totality of potential contrasts of meaning encoded in grammar but which originate in social life. An analyst can interpret these social meanings and their

historical–ideological context of culture in any text. Literary and nonliterary texts are the same in this respect.

We begin with the social system, since it is here meanings are made. The multidimensional sources of human significance are interactively created and exchanged in semiotic systems. This 'making of meaning' occurs in social institutions and their recurring social contexts or situation types. Such situations are themselves semiotic constructs—we can recognize them and what they 'mean' within our culture. Each type has three dimensions relevant to potential meanings (1):

field = social activity performed
tenor = social roles enacted
mode = the role of language in the situation. (1)

'Mode' includes both channel (written, spoken, etc.) and genre (literary, 'narrative,' 'lyric,' etc., and nonliterary, 'interview,' 'casual conversation,' 'argument,' etc.) (see also *Genre*). The genres, or rhetorical norms, available in a culture precode language to perform the social activities and roles of each situation type and thus enable language to play the constitutive part which the social system demands of it as regards 'field' and 'tenor.'

The language system functions in these contexts of situation and, Halliday argues, it has been shaped to do so. 'What can be meant' falls into three functional domains which serve the three aspects of situations. Language functions (2):

ideationally = to represent experience
interpersonally = to enact social relationships
textually = to create text relevant to situations. (2)

Each function interprets the 'meaning potential'— 'what can be meant'—in a given situation type. Out of the whole range of potential semantic contrasts, speakers statistically enact only *some* in a situation. This situationally constrained set of options is a register; 'the necessary mediating concept that enables us to establish the continuity between a text and its sociosemiotic environment' (Halliday 1978: 145). By analyzing these meaningful choices, as realized in the grammar and lexis instanced in a text, we can interpret its register and thus how the text is functioning to both enact and create a social situation.

2. The Interpretation of Text

The above theory provides a framework for the statement of ideational, interpersonal, and textual meanings. It is the task of linguistic analysis to analyze such patterns of encoded choice. But a reader's interpretation also involves contextualization of textual patterning at a higher level. This process is relative to the reader's social positioning, critical practices, and ideological interest within the context of culture. Some 'higher level semiotics' of the culture (see Sect. 1 above) become relevant. A literary text, produced and consumed in situations within the social institution of 'literature,' also makes relevant a 'literary universe of discourse' and 'literary norms and assumptions' including the body of other literary and literary critical texts. It is the job of the linguist to describe this process of interpretation— how a text might be understood. And although subjective relativity and hence indeterminacy of readings is normal, it is also assumed that there is some community of the plausible which is replicable across readers based on common linguistic and cultural resources (Halliday 1971, Birch 1989).

There is no mechanical procedure for interpreting, merely various heuristic practices. However, some textual patterns are prominent. If this prominence figures in interpretation in terms of higher level semiotics, then it is seen as 'motivated prominence' or 'foregrounding' (Halliday 1971; see also *Style*).

The analyst approaches foregrounded patterns first of all in terms of the choices they exhibit according to the functions of language. How is a world represented (see *Representation*)? How does the speaker reveal him or her self and manipulate the addressee? How does the 'texture' of the patterning relate it relevantly to itself, its cohesion, and to its contexts of situation and culture, its coherence in terms of higher level semiotics? The analyst intertwines description with higher level interpretation, each guiding the other.

Most analyses concentrate on the 'representativeness' of a text world in terms of the semantics of processes and participants (see *Representation*). Halliday (1971) studies Golding's *The Inheritors* in this way and contrasts the represented world of a Neanderthal community with that of early man. In an influential article, Burton (in Carter 1982: 194–214) subjects a passage from Plath's *The Bell Jar* to a similar analysis and pointedly interprets the foregrounded representation in terms of the higher level semiotic of feminism. Two articles which survey this approach are Kennedy (in Carter 1982: 83–99) who analyzes Conrad's *The Secret Agent* and Joyce's *Two Gallants*, and Simpson (1988) where the opening of Le Carré's *The Little Drummer Girl* is treated. Much of this analytic work has a usefully pedagogic orientation (see Carter 1982, especially the Introduction: also Brumfit and Carter 1986, Carter and Simpson 1988). In the work of Fowler (1981, 1986) we find emphasis on all three functional domains but increasingly on the interpersonal dimension of literary texts, an orientation he explicitly connects to the dialogism of Bakhtin (see *Dialogism*, see also as regards the interpersonal, Weber in Carter and Simpson 1988: 95–111, Toolan in Birch and O'Toole 1988).

3. Sovereignty and Reregistration

The functional patterning of a text is also interpreted in terms of the field, tenor, and mode of its context of situation. The situations enacted provide another route upwards to higher level meanings.

In literary texts such contextualization is on two levels (Halliday 1978: 146). On the first level, the text is related to the social situation of its *own* production and consumption. One can talk of the 'field' of verbal art, the 'tenor' of the authorial presence (the 'implied' author and reader) and the genre, the conventions of which preshape and enable these. This is the context of literary theory and the sociology of literature. Halliday (1978: 145–50) provides such a context for a Thurber fable. The second level is produced by a general feature of the first level. In literary texts, the immediate social environment does not determine the form, except via its genre. Compare this with a practical situation like buying a bus ticket where the language actually achieves the buying and this determines what is meant. By contrast, the literary text 'creates its own immediate context of situation'; the text is 'self-sufficient' (Halliday 1978: 140–6). By deploying a pattern from *anywhere* in the language, the author recreates that situation and its higher level meanings and thus a virtual reality, the text world, through language. For example, deployment in written mode of the register of casual speech 'creates' a virtual situation in which inferable 'personae' spontaneously speak.

Carter and Nash (1983) label this feature of literary texts 'sovereignty.' They write, 'this denotes the self-supporting capacity of the text, its power to generate and develop a pattern of meaning, without reference to externals and without requiring of its readers any prior knowledge other than the common stock of experience' (Carter and Nash 1983: 130). This generic displacement from the exigencies of immediate demands permits a literary text to utilize any register and paradoxically, through its very self-sufficiency, to integrate the social meanings made outside the literary universe of discourse into the literary text. This process is termed 'reregistration' (Carter and Nash 1983: 129). The imported meanings both add an extra layer of contextual meaning to the text (a form of equivalence not noted by Jakobson 1960) and the allusive register items take on new meanings or interpretative potential in the new text. Reregistration is an important contributor to the characteristic polysemy or semantic density of literary texts (Carter and Nash 1983: 120, 140). This register identification across texts is one important dimension of intertextuality.

Carter (in Steele and Threadgold 1987: 442) illustrates reregistration by demonstrating the language of the travel brochure or geography book in a work of fiction and cites the use of journalistic and historical forms in Rushdie's *Midnight's Children* and *Shame*. Auden's employment of 'officialese' in *The Unknown Citizen* is cited by Carter and Simpson (1988: 22; see also Fowler 1981: 29–32 for an analysis of the registers of bureaucracy). O'Toole (in Birch and O'Toole 1988: 12–30) demonstrates the interaction of two registers in Reed's *Naming of Parts*. Carter and Nash (1983: 129) point out how even a single technical expression like 'double indemnity' from the register of insurance when deployed as the title of a crime novel takes on a new relevance and generates an extra layer of meaning in that literary context. Simpson (1988: 12ff.) investigates reader responses to the Le Carré passage mentioned above (Sect. 2). He finds that 'the basic novelistic format has been overlaid by elements of a tourist–travelogue register' and his informants recognize this as well as the text genre as 'thriller–spy novel' (see Simpson 1988 for further references to examples of reregistration).

4. Issues and Outlooks

Is literature itself a register? This is the issue of literariness (see *Literary Language*). We ask whether the functioning of language in literary situations itself generates characteristic patterns of choice. Some sources talk as if this was the case (see Halliday 1983: xi). Others adamantly deny it (Halliday in the foreword to Birch and O'Toole 1988: vii, Simpson 1988).

Reregistration suggests that literary situations do not constrain authorial options because linguistic patterns from any situation can be deployed. If register is a probabilistic 'linguistic' pattern of semantic options, then all patterns are unpredictably equiprobable in a literary text. However, it has recently been claimed that such deployments, producing 'register mix,' are a characteristic of many texts. O'Toole writes '. . . texts are not simply 'instances' of register but institutionally determined, multiregisterial discourses . . .' (Birch and O'Toole 1988: 111–25). Hudson (1980: 49) sees register as the output of a speaker's internalized norms. In this respect, a speaker's utterance would convey, like a dialect or accent, that particular mix of social meanings he or she opted for out of a multiplicity of norms, perhaps in a situation of normative conflict or lack of focus. The statistical realization of this register mix would precisely convey that mix of meaning.

In spite of sovereignty and reregistration, it is clear that literary texts do function in first-level social situations, those in which they are produced and consumed, and these must somehow relate to their linguistic patterns. The normative nonlanguage factor that relates situation to text patterns is not register but genre. It is there that we find the normative dimension of literariness (see *Genre*).

261

It is also through genre, as a contingent historical part of situations, that the language itself is related upwards to the social institutions (education, publishing, literary criticism, etc.) and social practices (methods of reading, generic conventions, etc.) that construct literariness with respect to its function in societies (see Fowler 1981, Kress, in Birch and O'Toole 1988: 126–41). Pointing downwards to language choice, the genre specifies those sociohistorical clusters of text pattern that are recognizably 'literary,' for example, Simpson's 'basic novelistic format' above. Such a text will mix and interweave reregistered items and generic texture in a rich brew which exhibits literariness, no feature of which is found only in literature. This 'pattern of patterns' functions to enable the inferential methods of reading which have evolved in literary institutions, which in turn function ideologically in some historical context of culture. It is a matter of terminology, but the first level generic features of literary texts might be seen as registerial, although paradoxically the whole 'mix' cannot, because of reregistration.

The main recent research in social semiotics integrates it with other contemporary trends. Some relates register to broader discursive practices and links functionalist stylistics to poststructuralist thought, Foucault in particular (see Halliday in Birch and O'Toole 1988: 31–44, Halliday 1987), Threadgold in Steele and Threadgold 1987: 549–97, Threadgold in Birch and O'Toole 1988: 169–204; (see also *Foucault, Michel*). Another trend is towards the critical analysis of language, ideology, and power (see Kress in Birch and O'Toole 1988: 126–41; see also *Ideology*). Social semiotic approaches to literature can also be closely related to discourse and pragmatic approaches in that all equally approach literary texts as a use of language in context.

Religion and Language

J. F. A. Sawyer

Religion has always played a role, often a very significant and even crucial one, in the history of language and linguistics.

1. Sacred Texts

Sacred texts have a central role to play in most religious traditions and the language in which they are written and read is often crucial. Sacred scripts or 'hieroglyphics' were sometimes invented with a special religious function, and exquisite calligraphy evolved as in Islamic art and the great monastic manuscript traditions of medieval Europe.

In Islamic doctrine, the Qur'ān represents the actual words of the deity delivered directly, in Arabic, to Muhammad in the early seventh century CE, and must only be read in Arabic. Thus for the majority of ordinary Muslims throughout the world, who have no knowledge of Arabic, translation into the

vernacular is officially discouraged and the Qur'ān is recited in the original language with amazing devotion and accuracy, but minimal understanding. Similar conservatism applies to the reading of Sanskrit texts in modern Hindu temples, Avestan texts in Zoroastrian worship, and Biblical texts in Hebrew, even in the more liberal Jewish synagogues. In some cases it is the language of a widely used translation that assumes this role as in some varieties of Christianity where Greek, Latin, Slavonic, Syriac, Ge'ez, and other versions, not to mention the King James Authorized Version, have been treated with the same awe as if they were the original text. The same applies to some versions of the Buddhist canon which are in most contexts preferred to the original Pali.

2. Special Languages

In addition to the languages of their sacred texts, many religious communities employ special languages or language varieties for other purposes. Glossolalia or 'speaking in tongues' is a conspicuous example where utterances in a language unknown to virtually everybody present has an important prophetic function. Untranslateable or 'nonsense' languages are a feature of religious rites among the Australian aborigines of northern Arnhem land, while some American Indian medicine men use an incomprehensible language when talking to each other or to supernatural powers. Probably as much for social and political reasons as for spiritual ones, Rastafarians have evolved a distinctive mode of speech among themselves, unintelligible to the outsider. The same applies to the cargo cults and several other new religious movements. Monastic sign language is another example of a special language evolved within a purely religious context.

There are many examples of the belief that everyday language is not sacred enough for religious purposes. They include the use of Sumerian in ancient Near Eastern rituals long after it had ceased to be a living language, of Sanskrit in Hindu worship, and of Ge'ez in Ethiopian Christianity, Syriac in Eastern Christianity (in Kerala in South India, for example, to this day), Hebrew in Judaism, and, until the twentieth century, Latin in the Roman Catholic Church all over the world.

The notion that no human language at all, ancient or modern, natural or artificial, is adequate, appears both in the well-known Quaker predilection for silent worship and in the 'language-transcendent' meditation techniques of some varieties of Buddhism and Christianity.

Within the context of a religious community meeting regularly for worship, special varieties of language are often used for public prayer, hymn-singing, and preaching, partly to heighten people's awareness of the sacredness of the moment, and partly to highlight the continuity of what they are doing with the worship of other communities elsewhere. Thus, for example, Jews all over the world using precisely the same Hebrew words as their ancestors have used for generations, as they celebrate Passover or Yom Kippur ('the Day of Atonement'), experience a sense of solidarity as 'God's people' which would not be possible if any other language was used.

The same applied until the twentieth century to the use of Church Latin in the Catholic Mass, and to the distinctive English of the 1661 Book of Common Prayer in the Church of England. The introduction of the vernacular into worship places the emphasis more on communication and the fuller participation of the people, although the precise wording of the modern Catholic 'Missal' and of the Anglican 'Alternative Service Books' is still controlled by the ecclesiastical authorities. Conservative opposition to using the vernacular in worship is common as in the case of the Anglican 'Prayerbook Society,' dedicated to preserving the use of the 1661 Book of Common Prayer.

The dynamics of prayer in which human individuals believe they are engaged in dialogue with a deity or saint, also determines the variety of language adopted. In the language of hymns, too, metrical constraints, the popularity of traditional melodies, and other factors lead to the survival of bizarre archaisms which would rarely be heard outside that special context. Frequently, tension between a desire to uphold an ancient religious tradition, by preserving Latin or Hebrew or Sanskrit, for example, and a move towards making public worship more generally intelligible, has produced interesting compromises. The need to train preachers in the use of a language variety designed to elicit the appropriate response, has produced elaborate homiletical strategies down the ages, particularly in Christian tradition.

3. Beliefs about Language

Belief in the power of language to influence reality is expressed in many ways all over the world. In European tradition this implies a Platonic view of language in which there is a direct connection between the world of names and the world of things. The Chinese doctrine of the 'rectification of names' was similarly based on the belief that there is (or ought to be) a formal correspondence, between names and functions, titles and duties, especially in politics. In Hindu philosophy the sacred sound *om* was understood to be the consummation of the Vedas and as such to denote their ultimate referent Brahman, source of all intelligibility and being.

Personal names are believed to have special powers, and great care is taken by many communities to protect their children by naming them according to a set of carefully controlled rules. Some African

263

tribes give their children unattractive names to make them uninviting to evil spirits. In some American Indian and Australian Aboriginal communities, the name of a recently deceased person is taboo, and even words that resemble it are meticulously avoided. Jews at one time changed the names of their children to deceive the angel of death, and the name of their God was believed to be surrounded by such a powerful aura of sacredness that it was never to be pronounced except by the High Priest in a very special ritual context. Some Christians apply a similar taboo to the name 'Jesus' in the late twentieth century.

Written language has a special role to play in this respect as beliefs about the Hebrew alphabet and the Tetragrammaton in Jewish tradition illustrate. Egyptian hieroglyphics, Nordic runes, and Chinese characters also have a long and fascinating history of magical uses and beliefs.

Several religious traditions believe in the creative power of the divine word or command: in Ancient Egyptian tradition the god Ptah created heaven and earth by his word. The same creative power is attributed to the word of the god Prajapati in Hinduism, and to the creator god of Jews, Christians, and Muslims. In Hindu iconography, the god Siva Nataraja ('Lord of the Dance') is represented as producing the sound which creates, sustains, and destroys the world. Highly complex mythological and doctrinal elaborations of this concept appear in Hinduism, Christianity, and elsewhere.

Primary myths about the origin of language, on the other hand, are surprisingly rare. The biblical stories of Ham, Shem, and Japheth, the three sons of Noah, and of the Tower of Babel, an elaborate West African example from the Dogon of Mali, and a passing reference in Greek mythology seem to be exceptions. Maybe the focus on language as a key to understanding human nature and society is a modern one.

In striking contrast to this situation are the many modern 'secondary myths,' clearly motivated by political and social factors, including sixteenth-century claims that Adam and Eve spoke a Teutonic language and that the Mayan script was of Semitic origin, and more recently, quite blatant attempts to prove the superiority of the Aryan race—or the Semites or the Africans—by the use of linguistic evidence.

4. Influence of Religion on Linguistics

The belief that, to be effective, ritual utterances, frequently in a language or language variety other than that of the priests performing them, have to be recited with absolute accuracy, has had profound effects on the history of language and linguistics. In the first place, it means that religious authorities insist on a very large part of their educational

programs being devoted to language teaching. Thus the training of Catholic priests, Jewish rabbis, Muslim imams, and Hindu brahmins had to include the study of the ancient language in which their scriptures and their liturgy were written—Latin, Hebrew, Arabic, Sanskrit, respectively—whatever their mother tongue was, and whatever the language of the people they would be working among. At the same time, religious schools are set up in which children are taught at least the rudiments of the appropriate language to enable them to recite texts correctly from an early age. Muslim Qur'ān schools are a good example. In many cases religious institutions exert, or are bound by, legal authority to preserve and protect the sacred language. This applies as much to the vernacular wording of the modern Catholic Mass and the English of the Church of England liturgy, as to the sacred languages of Judaism, Islam, and Hinduism. The effect on the survival or spread of such languages and language varieties, as also on perceptions of their superiority above indigenous or colloquial languages and dialects, can readily be appreciated (see *Linguistic Imperialism*).

Second, elaborate scribal and grammatical techniques were worked out to ensure that the sacred text was accurately transmitted. Thus ancient languages which might have been totally forgotten have been preserved in the context of religious institutions of many types. A very large proportion of the linguistic material that has survived from the ancient world is of a religious nature, preserved in temple libraries and the like. Scribes engaged in copying a sacred text, the Jewish masoretes, for example, worked under the strictest rules governing every aspect of their craft. They also devised elaborate systems of 'pointing' to preserve correctly every minute phonological detail, including cantillation marks, after Hebrew had ceased to be their first language. This and other developments, especially contact with Arabic grammarians, led eventually to the emergence of Hebrew linguistics.

In early Hindu tradition, by contrast, the primary form of language was speech, not writing. The Vedas are regarded as *śruti* 'hearing,' to be transmitted word-perfect from generation to generation. Here too the linguistic precision required led not only to some astonishing feats of memory, but also to the appearance of some remarkable pioneers in the history of linguistics, of whom Pāṇini is certainly the most celebrated.

Finally, the communication, interpretation, and translation of sacred texts have influenced language and linguistics in a number of significant ways. The history of Bible translation is by far the best documented example of this. In many languages, such as Gothic and Old Church Slavonic, as well as countless modern spoken languages in Africa and

Asia, the Bible was the first text to be written down. In many cases new writing systems had to be devised, while others like the Korean Han'gŭl system, came to be more widely used as a result of the efforts of Bible translators, so that they were no longer the possession of an intellectual elite. It is probably true to say that, because of European colonial and postcolonial educational policies, there is still very little published in most of the African languages except for church purposes.

Important contributions to all branches of linguistics have been made as a result of the activities of Christian scholars and missionaries, from the early pioneering work of men like the Jesuit Matteo Ricci (1552–1610) in China and the eighteenth-century English Baptist William Carey in India, not to mention St Jerome and Martin Luther, to the more recent and more technical research associated with the Protestant Bible Societies, the Vatican (where incidentally there is still a thriving Latin Department), and the Summer Institute of Linguistics (see *Missionaries and Language*). As a result of their work, many languages and dialects were recorded for the first time, and the first grammars and dictionaries produced. Theological controversies, like the 'term question' in nineteenth-century China, focused for the first time on important semantic issues, and some recent advances in comparative semitic linguistics are due to the activities of a new generation of biblical scholars.

The effect of Buddhist missionary activities, especially in Central and Eastern Asia, has been considerable too, but less well-documented. It appears that Buddhist teachings were from the beginning translated into regional languages and dialects. The early history of translation into Chinese, for example, can be traced for 1000 years, from the earliest attempts by polyglot monks in the second century BCE, to the establishment of official translation bureaus. It was for the purpose of translating the Buddhist canon into Tibetan that the Tibetan script was created in the seventh century CE, and this in turn was used as a model for the Mongolian writing system, created under the patronage of Kublai Khan in the thirteenth century.

Slang: Sociology
I. L. Allen

Slang is more a sociological than a purely linguistic idea and is best understood in the theory of modern society and culture. Dictionaries usually define slang with at least two senses. First, slang is the special, restricted speech of subgroups or subcultures in society and, second, it is a highly informal, unconventional vocabulary of more general use. This article is concerned with both senses, but especially with why and how restricted subgroup speech becomes general slang. Slang in use is a marker of social differences and, as such, is a vocabulary that has become used and understood with social purpose beyond the boundaries of the subgroup that originated the lexical items or their special meanings.

1. Origins

Slang first emerged in abundance where diverse peoples met at the cultural crossroads of the ancient market city; it flourished in the more diverse and occupationally interdependent medieval city. For the same but more complex reasons in the nineteenth century, slang became part of the life of modern cities, or more validly today, of modern society in general. By its very nature slang emerges from the organization of diverse society and in small ways serves both to maintain and to change social structures, or the power relationships among social groups. Slang is a necessary and inevitable cultural product of a plural, complex, dynamic, and highly interdependent modern society.

The word 'slang,' of uncertain origin, has been dated to about 1750 and was soon thereafter defined at least once as 'street language.' Slang originally denoted cant, or the restricted speech of the low, often criminal classes of society. However, the idea of slang gradually evolved to denote other subcultural speech, both high and low, as well as more general but unconventional vocabulary. By 1890 slang had taken on its present sense of a level of language below standard and of a body of lexemes derived from yet lower and more restricted levels of speech. The more general idea of popular speech, which includes slang,

265

is today coming into a newer and wider use by language scholars. Popular speech encompasses older forms of folk speech, which are associated with rural society and with the oral tradition, and newer forms of folk speech, often slang, which are associated with cities and modern society and with the mass media. Popular speech includes both spontaneous folk expressions and popular locutions prompted by the mass media. Sociologically speaking, slang is the urban part of popular speech and has historically found many of its incentives and referents in the socially diverse urban setting.

2. The Late Twentieth-century Idea of Slang

Slang is not a class of lexemes that can be described and then circumscribed and does not differ from standard or other levels of speech in any purely linguistic characteristic. Every effort to define slang as a kind of vocabulary has failed to cast a net wide and fine enough to catch all that looks, feels, sounds, and works like slang. The indefinite class of words labeled slang in general dictionaries or included in any dictionary of slang will testify to this problem. Nonetheless, dictionaries usually characterize slang by describing its informality, unconventionality, ephemerality, ellipsis, bizarre metaphors, playfulness, and the like. People of a Whitmanesque bent have said that slang is the poetry of everyday life and the free and natural speech of the common people. While slang expression is acute, the metaphors occasionally brilliant, and it sometimes alliterates and rhymes, slang is more a level or register of speech than a poetic form of the folk (see *Literary Language*).

For practical lexicographers, slang is a 'place,' a way station and a proving ground for cheeky new words and phrases. The label of 'slang' is a necessary one for lexicographers who are obliged to indicate levels of usage to guide dictionary users. The most neutral and unassailable definition of slang is simply that of a level of usage (Flexner 1974). Slang is 'below' standard and 'correct' informal usages and socially is less acceptable in formal discourse. On the other hand, slang is more widely used or at least more widely understood than restricted subgroup speech, such as regional and social dialects, argot, cant, or jargon. In this sense, slang is 'above' subcultural speech, where so much slang began its upward and outward-bound career into general usage.

Viewed as a level of usage, slang is vocabulary in limbo. Slang is, so to speak, applicant language that is awaiting acceptance or rejection by standard usage, or endlessly awaiting neither—and perhaps quiet withdrawal. Slang has at least four resolutions (Maurer and High 1980). If an item of slang proves durable and virtuous in the usage of the general public and, to a lesser extent, in the eyes of arbiters of elite usage, it may enter standard usage, as much slang has and does all the time (e.g., *movies*). Or it

may remain slang for years, decades (e.g., *cool* 'very good'), or even centuries (e.g., *to snitch* 'to inform'). Or it may be tried out, found wanting, redundant, or boring, and returned to the worldly regions of its subcultural origins, or perhaps just assigned the stigma of datedness (e.g., *to dig* 'to understand'). Much slang just disappears, not to be heard from again (*wizard* or *some pumpkins!* 'superb!'), unless resuscitated in later years (*pig*, 'a policeman' in the 1840s, was revived over a century later in the 1960s). All this is only the beginning of the story. Slang is too vital an idea to rest easily under the umbrella of popular speech or upon a rung on the social ladder of usage.

3. The Interactional Uses of Slang

The view of slang as a level of usage, or as a marker of social position in systems of difference, often of vertical stratification, however, opens the way to see the distinctive uses of slang in social interaction and foreshadows its larger sociology. The difference between standard, proper, or elite speech, on the one hand, and low, unconventional slang, on the other, provides the tension that enables slang to serve as a language of social opposition. The role of slang in subcultural confrontation has long been known but perhaps not generally appreciated. Slang is a class of language used, among other social and psychological uses, to deny allegiance to genteel, elite, and proper society and to its standard linguistic forms. Slang is thus used to assert social opposition, ranging from the most vicious and hostile verbal aggression to the gentlest, teasing contrariness and playful disruptiveness. The utterance of subcultural words and phrases is also a way to seek bonds with sympathetic others and, as a new group, to oppose or just to break with the dominant tone of discourse. Slang in any case is used earnestly or playfully in order to lower, or to shift laterally, the register of discourse.

Dumas and Lighter have articulated this view and call for the retention of the concept of slang in linguistics to denote a functional category of lexemes that 'are identifiable primarily by the intent (or perceived intent) of the speaker or writer to break with established linguistic convention.' They also note another basic distinction of most slang: 'Slang characterizes a referent; jargon and standard English only indicate it' (Dumas and Lighter 1978: 13). The social utility of slang, then, lies in the disruptive rhetoric it produces and using the speech of stigmatized subcultures is one way to lower the register (see *Register*) of discourse (Lighter 1994).

Slang also facilitates a variety of distinctive interactions in modern society, insofar as it retains widely recognizable subgroup origins and meanings. Slang is used to manage the multiple, overlapping, and shifting identities of modern life—a world of

'masks and mirrors.' A skill of city living, for those who adventure into its diversity, is knowing the subcultural talk of other groups. This knowledge is a way to attribute meaning to the seeming jumble and noise of modern life. The anonymity and public life of the large city, especially, offer many opportunities for interactional games, deceptions, identity switches, and opportunities for impression management for either fun or profit, and slang with subcultural associations facilitates these manipulations. Slang, for example, may be used to signal that the speaker is conversant with, or maybe even belongs to, a subculture of titillating or prestigeful reputation. The use of subcultural speech becoming slang, then, is often a tame adventure in verbal slumming, or in social climbing.

4. The Essential Urbanness of Slang

Modern slang is a distinct level or register of language that arose during the Great Transformation from homogeneous rural to heterogeneous urban society. While in principle, general slang can arise in any situation of social difference, the modern industrial city in the nineteenth century intensified every material condition that creates slang: the aggregation of large and variegated social groupings, their proximity and high visibility to one another, the complexity of their economic interdependencies, and the necessity and desirability of contact and exchanges of every sort. Heavy migration and settlement in ethnic enclaves of the great cities influenced slang throughout the nineteenth century and are influencing it again at the beginning of the twenty-first century. To this potent mix was added the intensifying ingredient of common knowledge of the city through the mass media, especially the newspapers and the comics and, in another medium, the popular cultures of minstrelsy and vaudeville.

The lexicographer Stuart Berg Flexner developed the idea of slang in diverse society (Flexner 1974). General slang and other nonstandard varieties of language can arise only in the presence of third parties or subgroups in society—the primitive urban situation. Flexner suggested a simple sociology of number, in both the grammatical and numerical senses, that is reminiscent of the triadic theory of the German sociologist Georg Simmel (Wolff 1950: 135–6). Slang develops when the conversation between the first and second persons, who have agreed upon a common language, begins to include the speech of third parties or subgroups and thus to allude to other, external meanings and realities. General slang is, thus, an epiphenomenon of diverse urban society and, by sociological definition, can exist only in plural societies of multiple, interacting social worlds.

Historically, cities have been generators of cultural and technological innovation, new forms of social organization, new social varieties, new forms of inequality and, thus, of lexical innovation to express these new thoughts and new social objects. American slang, however, is often traced to the period after the War of 1812 when the old frontier set the emerging tone of American speech with, in H. L. Mencken's words, 'its disdain of all scholastic rules and precedents, its tendency toward bold and often bizarre tropes, its rough humors, its not infrequent flights of what might be called poetic fancy, its love of neologisms for their own sake.' Yet 'to the immigrants who poured in after 1850, even the slums of the great Eastern cities presented essentially frontier conditions' (Mencken 1963: 148).

Language scholars of a social bent have long associated slang with cities and urban society. John Camden Hotten, the London publisher and lexicographer of slang, in 1859 wrote in the preface to his early compilation that the most favorable conditions for the appearance of slang are those of 'crowding and excitement, and artificial life' (Hotten 1859: 35). Or, to elaborate this observation for the end of the twentieth century, slang grows from the density, intensifications, and social releases of urban life, in contrast to life in traditional, homogeneous, or rural communities. The philologist George Philip Krapp wrote that, in general, slang 'is found in the speech of persons whose social relations are extensive, varied, and animated. It is the product of the city rather than the country, of sophisticated rather than naive society' (Krapp 1925: 317). Eric Partridge, noting the presence of slang in Ancient Greek and Latin, wrote that 'knowing the characteristics of urban life, we may assume that slang dates from the massing of populations in cities' (Partridge 1963: 37).

Yet general slang can arise in markedly nonurban places, as Partridge and others so abundantly found in the military, where slang served as a freemasonry of speech among persons of diverse backgrounds. Slang can arise in any place that simulates the social diversity of the cities and where diverse peoples meet, even at rural crossroads, or in any situation where people of different social ranks meet and, at least initially, culturally oppose one another. In principle, general slang can arise from the most rudimentary differences of social role, in any situation where third-group locutions can be introduced.

Large metropolitan centers have been the most fertile producers of slang about all things. Anglo–American commentators on slang throughout the nineteenth century regularly associated slang with big cities, especially New York and London. Early lexicographers collected the distinctive vocabularies of various urban groups; they noted the role of the printed mass media in the diffusion of slang; they contrasted stable rural dialect with the bizarre fleeting talk of the big cities; they noted the origins and use of slang in high society as well as in low; they

understood its uses in social opposition; and they glimpsed the principles of diffusion. Population density and crowd psychology in the streets did the job of circulating slang that mass communication does in the late twentieth century. In 1852 Charles Mackay, in his essay 'The popular follies of great cities,' marveled at how the catch phrases, such as *quoz, Oh, what a shocking bad hat!*, and *flare up*, seized the lower orders of London. 'London is particularly fertile in this sort of phrase,' Mackay wrote, 'which springs up suddenly, no one knows in exactly what spot, and pervades the whole population in a few hours, no one knows how' (Mackay 1980: 620).

Throughout the modern period down to, say, 1950 one may well be struck by the number of words and phrases in slang that denote the essences of city life. Segmental, impersonal, and often exploitative social relations were expressed in the idea of the city as a *jungle*, an employment agency as a *slave market*, or in the irony of *my uncle* 'a pawnbroker.' An awareness of class and ethnic differences were expressed in hundreds of well-known ethnic slurs and similar class derogations. Personal appearances and styles of dress as seen in city streets are recorded in terms such as *plug ugly, jelly bean, dude*, and *gussied up*. A variety of urban social locations and roles were expressed in *lounge lizard, ritzy, rubbernecker, skid row, coontown, black-and-tan dive, the 'burbs*, and in other slang denotations of urban class and status. Unconventional styles of life and bizarre occupational specializations were denoted in *panhandler, mushroom faker, taxi dancer*, and *sandwich man*. The importance of money is apparent in the many slang synonyms for money, often ill-gotten, and the lavish spending of it (*big spender* and *butter-and-egg man*). Sexual and other social relations that are casual, segmental, impersonal, commercial, and exploitative are implicit in *sugar daddy, gold digger, hooker, pimp, bouncer, puller-in*, or *steerer*. New experiences of every kind in the industrial city, including its machines, were amply denoted in slang: *bus, taxi, el, rattler* 'a streetcar,' *skyscraper*, or *an Ameche* (passingly, 'a telephone' about 1940 and an allusion to the actor Don Ameche who played the inventor Alexander Graham Bell in a popular movie).

Moreover, the semantics of slang, especially its names for kinds of people (ethnic, class, and other social types), display a pervasive structure of vertical stratification and binary opposition, frequently expressed in invidious distinctions between 'Us' and 'Them.' Slang is greatly about the new and different and, in the social realm, often expresses stressful social relations and a dislike for the unlike.

5. The Urban Sociology of Slang

Slang derives from the multiple subcultures of urban, that is to say modern, society. For the most part it denotes vocabulary that has diffused through and perked up into wider use from myriad intersecting social circles. The neoclassical or subcultural theory of urbanism explains how cities create a variety of subgroups and subcultures that vary in number directly with population size (Fischer 1975). Large cities attract as migrants large numbers of different kinds of people, who then join and enlarge the diversity of groups already in the city. The greater numbers of people with specialized interests in cities provide the sufficient numbers or 'critical masses' that enable subcultures to sustain and intensify. Eventually, nascent subgroups within larger subgroups reach the numbers necessary and sufficient for even more specialized interest groups to break away and form yet other subcultures.

The many direct and indirect contacts and communications among most subgroups in the dense, compact, intensely interactive market city, as people learn more and more about one another, cause some subcultures to become more alike, in some cases even to assimilate or merge into one. Other groups recoil from the culture clash they experience and, as a result, entrench, reaffirm their original identities, and become even more different than before. The city, precisely because of its large size, density, and social variety, creates a continual process of sustaining, reinforcing, and creating ethnic groups, social classes, styles of life, and every imaginable kind of subculture, including many so-called deviant ones. As a necessary part of this process, many meanings are exchanged, which results in the learning and diffusion of borrowed subcultural words and phrases. The creation of subcultural speech, intergroup contact, and the diffusion of these words through intersecting social networks into wider usage, or into general slang, recapitulate and illustrate Fischer's modified theory of urbanism and may be taken as a special application of it.

Most general slang comes from the restricted, special vocabularies of these many subgroups in modern society and becomes slang as it diffuses through the word-of-mouth networks and between the intersecting social circles that lace together much of the whole society. The diffusion of lexical innovation follows the same principles that govern the diffusion of any cultural innovation: it spreads in direct proportion to population density, intensity of communication and—above all—perceived usefulness in social interaction. In this way, restricted subcultural usages pass into general or at least into wider usage, often with the augmentation and amplification of the mass media.

In the process of diffusion, the subcultural expression becoming general slang often changes meaning to some degree, usually widening in denotation and

connotation, and so becoming useful in more social situations. If the word or phrase proves useful or amusing in its new social setting, it may pass further into more and more circles until it reaches a wide enough audience, who at least understand its meaning, to say that it is in general slang and part of the general culture. If such slang stays in wide use for decades, it may lose its subcultural associations and seem just to be there in the language, its subgroup origins remote or forgotten.

More than half of historical American slang, it has been estimated, came from the chiefly male subcultural speech of lumberjacks, railroaders, musicians, hoboes, sportsmen, show business, teenagers, college students, ethnic minorities, the military, and various deviant subcultures, such as criminals and drug users (Flexner 1960). Subcultures, as the prefix of the term implies, were once thought of as little social worlds that were 'below' the general culture or ones that were marginal to society or isolated within it. The idea of subcultures more validly embraces all subgroups of society, including social classes, genders, variant sexual interests, all majority and minority ethnic groups, regional groups, age groups, and a host of occupational, life-style, and consumer cultures, as well as all the groups more traditionally described as subcultures. A subgroup is any set of people generally linked in communication and bound by a common interest. These groups vary greatly in their level of organization and degree of self-consciousness. Ultimately, almost any distinguishing set of common experience and meaning can be described as a subculture of a subgroup. Everyone, it follows, belongs to multiple, overlapping subgroups and subcultures, the number depending on the variety and breadth of their interests and social engagements. The general culture of a society is the meanings and values that most of its subcultures have in common, and this includes its language and general slang.

Many subcultures, some of which may be called speech communities, have their own dialects or varieties of English in degrees of distinction from standard speech. Each variety, and most are merely nascent, may include distinctive pronunciations, special words or special meanings of ordinary words, or even grammatical differences. These special words, or as often ordinary words with special meanings, sometimes escape their little social circles or leak into one or more intersecting or tangential circles, where they are provisionally adopted. The subcultures of male homosexuals, drug users, and lower-class blacks are examples of leaky subcultures whose special words and phrases diffused into the general culture and its slang in the 1960s and 1970s (Maurer and High 1980). Previously, these subcultures were structurally tighter, or more isolated, and their words leaked out slowly and were transmitted largely by word-of mouth. The diffusion, or at least knowledge, of their norms was accompanied by the diffusion of their language, especially through the mass media. At the beginning of the twenty-first century such stigmatized subcultures are much less isolated and more subgroups of all kinds are leaking lexical expressions of their cultures—and leaking them faster—especially through television and the movies. Adopting slang, heard either in interpersonal or in mass communications, is a traditional way young people flirt with forbidden and other attractive subcultures.

The mass media can bring almost instant lexical diffusion. Mass-communicated slang and neologisms initially leapfrog communities and are introduced at once into many thousands of local social circles. If they catch on in many of these circles, they have a big headstart in the diffusion process and spread even further by word-of-mouth, now able to go like multiple brushfires through the verbal culture of a society. Slang-like advertising slogans, for example, are repeatedly reimplanted in local networks, from which they are sometimes spread from person to person. In modern societies laced together by the mass media, folk lexical culture (categories invented by people) blends with mass lexical culture (categories invented by media writers for people). This is how almost all new words now spread, slang or not.

6. Slang at the Beginning of the Twenty-first Century

In the past slang has been used more by men than by women and more by younger than by older people. In this sense, general slang itself was a semirestricted vocabulary of youthful male subculture and reflected its distinctive social construction of reality. But this is changing as gender and age subcultures merge a little in their social experiences. Much historical slang came from stressful male social worlds of the barroom and brothel, the life of tramps and hoboes, rough occupations, the military, sports, and deviant subcultures. Sociolinguists report that, until the 1970s at least, women used less slang than men and, even if they knew its meaning, used it in fewer social situations. Proper English signaled proper behavior, and the avoidance of slang reflected the greater pressures on women toward conventional behavior, at least in mixed company.

These subcultural walls are breaking down as women move into male preserves and so into situations of greater cultural variety and clash, which prompted male slang in the first place. Even low-register sexual and scatalogical expressions used as slang hardly raise an eyebrow in gatherings of sophisticated young men and women. Such vulgar and taboo expressions were formerly the restricted speech of male subculture, which is today losing its exclusiveness and isolation. Yet slang remains to some extent the province of the young—of socially

engaged young men and women. The cultural boundaries of yet other social categories—ethnic, class, style of life—are weakening as well.

In the more self-conscious atmosphere of cultural and linguistic relativism, slang is more acceptable in many situations, is no longer so shocking, and in a functional sense is ceasing to be slang—in a kind of postmodernist collapse of old social categories. At one time all slang, echoing rebellion and disrespect, might have raised eyebrows in the most formal contexts. But today some of the norms and useful parts of the language of deviant subgroups have been absorbed by straight society. The former, critical distinction of these different registers is diminishing. Slang depends on social differences, often tense hierarchies. If the norms and language of low-status outgroups were ever totally absorbed by elite ingroups, 'slang and gentility would die together' (Sledd 1965: 699). But new social differences and hierarchies are continually arising. Slang will certainly retain a role in the inevitable cultural conflict among them.

Speech and Writing
J. E. Miller

The contrast between spoken and written language is crucial for the study of human societies and language, affecting categorization, reasoning, the storage of knowledge, the running of societies, and the very concept of text (Goody 1977, Ong 1982). It relates to literacy and education, the social consequences of literacy and illiteracy, and the dissemination and control of information. Adopting a micro-approach, this article focuses on the grammatical, lexical, and textual differences between spoken and written language, indicating their implications for first language acquisition (including written language), language typology, and syntactic analysis.

1. Priority of Spoken Language

The priority of spoken language over written language is attested by various facts: no community has a written language only, though many have a spoken language only, and children learn spoken language first and most easily; every normal child learns the spoken language of its community, but some children fail to become literate. Nonetheless, it is essential to take account of the immense prestige of written language, its central role in literate societies, and the large divergences between the spoken and written varieties of what counts as the same language. Written language has a life of its own (Stubbs 1980).

The serious and publicly verifiable study of spoken language only became possible with the invention of the tape recorder, and only became widespread with the advent of the cassette recorder. The discussion below is based on various bodies of spoken language collected since the early 1960s: the Glasgow Map Task Corpus collected by Anderson and Garrod—here abbreviated to AG; the Human Communication Research Centre Corpus collected by Anderson et al. 1991—here A; the corpus of spontaneous conversation collected by Brown and Miller (1980)—BM; Kapanadze and Zemskaja (1979)—KZ; Höhne-Leska (1975)—HL; Macaulay (1991)—M; and Wackernagel-Jolles (1971)—WJ.

2. Spoken Language

The most obvious difference between spoken and written language, the medium of communication (vibrations in the air as opposed to marks on paper) is superficial compared with the deep, pervasive

differences, not just in grammar and vocabulary, but also in the general organization of discourse or text (cf. Ong (1982) on the psychodynamics of sight versus hearing, and see Sect. 3 below). Not every text that is spoken counts as genuine spoken language. The most interesting examples, because furthest from written language, are informal, spontaneous conversation and dialog produced during the performance of a task. These are what children are first exposed to, and represent typical adult linguistic activity. Other examples of spoken language are formal conversation, say on television, and (semi-) planned discourses such as lectures, sermons, and political speeches, which are closer to written language. Depending on circumstances, spoken narratives may be close to spontaneous conversation or written language or equidistant from the two.

These differences are important too because they have engendered different views among investigators on the nature of spoken language. The essential influence is experience of written language. The longer and more intense that experience, the greater its influence on an individual's speech. The data here, from speakers with no higher education and therefore with limited practice in written language, yield an analysis compatible with results from work on other languages but different from accounts such as those of Kroll (1977) and Halliday (1989), based on, respectively, the recorded discourse of undergraduates and observations of speech in academic communities.

3. Properties of Spoken Language in Contrast with Written Language

Spoken language is not degenerate written language but a different system designed for a different task. Language is discussed publicly only by literate speakers for whom writing plays a large role and who therefore see written language as basic and central and spoken language as an imitation (often unsuccessful) of written language. The historical facts are precisely the opposite. Written language is a later and specially elaborated variety developed over a long time by a small set of users. The major properties distinguishing spoken from written language are as follows.

First, informal spoken language is produced in real time, impromptu, with no opportunity to edit. Only the most skillful speakers can produce complex language in these conditions. Writing allows pauses for thought and editing, which enables writers to produce more complex syntax and to choose a wider range of vocabulary.

Second, spontaneous speech is subject to the limitations of short-term memory, which reinforces the no-editing effect.

Third, speaking is much faster than writing, and reading is much faster (and more effective) than

listening. That is, listeners must process instantly a rapidly produced and evanescent stream of speech, a task facilitated by simple syntax and simple vocabulary. Readers, dealing with permanent text which can be quickly scanned and reread, can process complex syntax and esoteric vocabulary, resorting to a dictionary if necessary.

Fourth, spontaneous speech is typically produced by people talking face-to-face in a particular context. It is accompanied by gestures, eye-gaze, facial expressions, and body-postures, all of which signal information. Gestures may signal attitudinal meaning, imitate the rhythm of speakers' utterances, and reinforce information encoded verbally, for example, a swift downward movement of the arm by a speaker describing a climber slipping down a slope.

Fifth, and finally, spoken language, especially informal spoken language, possesses resources of pitch, amplitude, rhythm, and voice quality which speakers exploit to the full. These resources are used to express emotion, to frighten, soothe, and cajole. They are widely used to convey reported speech; avoiding the special indirect-speech constructions of written language and phrases such as *so she exclaimed . . .*, *so she said . . .*, speakers signal reported speech only by a change of pitch, with appropriate voice-quality (see Brown and Miller 1980, Kitajgorodskaja 1988).

4. Grammatical Differences Between Spoken and Written Language

4.1 Sentences and Clauses

Written language is analyzed in terms of sentences, clauses, and phrases, and writers following the conventions of writing mark clearly the boundaries of units. (Of course, different societies have different conventions.) Spoken language, especially conversation with interrupted and overlapping turns, is hard to analyze, but phrases and clauses can typically be recognized unequivocally. The sentence is problematic. Clauses that could be written as one sentence occur quite independently, separated by long pauses and each with its own pitch contour. They may occur in different turns, either of the same speaker or of different speakers. Different listeners produce very different sentence-renderings of one and the same spoken text, as do speakers listening on different occasions to one and the same recording of their own speech (see Wackernagel-Jolles 1971). It is more appropriate to analyze speech as collections of clauses and phrases, the relations between the clauses being handled by discourse analysis, not sentence grammar.

These points are illustrated in (1) below, from dialog produced by one person instructing another how to draw a route on a map with certain landmarks, and in (2), from spontaneous conversation.

In (1), *taking a gentle curve south-west* in A's second turn relates to *you go down to the bridge*. The former modifies the latter, but one is led to wonder what criteria could be invoked to justify treating A's two turns as containing a split sentence. The sequence of turns is orderly, and it cannot be argued that A intended to produce a sentence with a main clause and a participial phrase, since A only produces the second turn in response to B's question. In (2), *where I capsized* is a relative clause modifying *canoeing*, the head and its modifier being in contributions from different speakers. The listener's task is to recognize *where I capsized* as a relative clause, and to find the constituent that it modifies. Just as anaphorical relations stretch across sentence boundaries in written language and must be handled by techniques of discourse analysis, so must clause relations in spoken language. The relevant technical term— 'clause-complex'—has been provided by Halliday (1989), who argues that the sentence is a unit of writing which has grown out of the clause-complex:

A: *you go down to the bridge* (1)
B: *uhuh—to the left of the swamp?*
A: *to the left of the swamp—taking a gentle curve southwest*

A: *the first day we went canoeing* (2)
B: *where I capsized*

4.2 Main and Subordinate Clauses

The distinction between main and subordinate clauses remains relevant to spoken language. In English and many other languages, the distinction is signaled by a complementizer or special word order, but the subordinate clause may be quite separate from any main clause. Subordinate clauses, being semantically incomplete, typically cannot function as the sole initial clause in a piece of discourse. (Note that all the clauses treated here as subordinate contain finite verbs; infinitive and gerund phrases were excluded.)

There has been controversy as to whether the proportion of subordinate clauses to main clauses in informal spoken language is less than in formal written language. The essential condition is long exposure to and use of written language, which is ensured by higher education. Having higher education is not of course a necessary precondition for the ability to use complex spoken language. Macaulay (1991) presents the proportions of subordinate clauses in narratives from working- and middle-class speakers in Ayr, Scotland. The percentage of subordinate clauses in the contributions of the working-class speakers ranges from 15.7 percent to 24.3 percent, with one score of 35.5 percent and a mean of 25 percent. The percentage for the middle-class speakers ranges from 22.7 percent to 32.5 percent, with one score of 45 percent from the best-educated person in that subset of informants and a

mean of 30.4 percent. If the single abnormal score in each group is removed, the mean drops to 20.3 percent for the working-class and 28.18 percent for the middle-class speakers.

The corpus described in Brown and Miller (1980) contains, inter alia, conversations between two 18-year-old girls from East Lothian, Scotland, containing discussion, jokes, and narrative. One (LS) had been accepted for study at university, and the other (AB) was hoping to collect enough qualifications to go to university too. For LS, the percentage of subordinate clauses is 26 percent; for AB, 25 percent. LS is middle-class and AB is working-class, but they both had six years of secondary education and their scores fall midway in the range of normal scores in Macaulay's study.

Macaulay (1991) further remarks that the social-class groups in his data differ in more than quantity. The middle-class speakers used more complement clauses, indirect questions, conditional clauses, and adverbial clauses of reason and concession, whereas the lower-class speakers used more adverbial clauses of place, time, and comparison. The data in Brown and Miller (1980) show a preponderance of complement and relative clauses, hardly any indirect questions (see Sect. 4.3) or indirect speech constructions, and a small number of adverbial clauses of place, time, reason, and condition. As mentioned in Sect. 4.1, many adverbial clauses, and some instances of relative clauses, were produced in different terms from the main clauses to which they related, and even by different speakers. Some types of adverbial clause were absent (see Sect. 4.5).

For comparison, consider the proportion of subordinate clauses in samples of different written texts: Penelope Lively *Judgment Day* (serious novel), sample 1—20 percent; James Herbert *Lair* (light novel)—24.7 percent; letters to *The Times*—29.7 percent; Bernard Levin centrepage article in *The Times*—30.9 percent; Penelope Lively *Judgment Day*, sample 2—31.6 percent; leaders in *The Times*—40.4 percent; article in *Geographical Magazine*—44 percent; Sperber and Wilson *Relevance* (monograph)— 46 percent. The mean is 33.4 percent, not far from either middle-class mean in Macaulay's study but much farther from the working-class mean. Only one written sample is as low as the working-class mean, and the academic texts are more than 20 percentage points ahead of it, a difference that is relevant to the discussion of literacy and education in Sect. 5.

The proportion of subordinate to main clauses for different groups of speakers of English is paralleled in speakers of other languages. Höhne-Leska (1975) claims that 65.23 percent of all sentences in the spoken language (German) are simple, that is, consist of a main clause only. The tables of data in Wackernagel-Jolles suggest a figure of 41 percent for the proportion of subordinate to main clauses in spoken German, but

that figure makes no distinction between speakers with and without higher education, and an inspection of the texts reveals large differences between the language of manual workers and the language of university professors and ministers of religion.

In the transcriptions of spoken Russian in Kapanadze and Zemskaja (1979), the mean proportion of subordinate to main clauses is approximately 24 percent. The texts are all produced by people with higher education, and the figures range from 30 percent in reminiscences by a senior university professor to 8 percent in an account of a camping expedition by a young scientist.

It is commonly supposed that the statement of, for example, conditions and concessions requires the appropriate type of subordinate clause. The supposition is wrong because speakers and hearers remember previous statements and draw on their knowledge of the topics under discussion and on their general background knowledge, both cultural and technical. Typically, speakers assume that hearers who cannot make sense of the communication will ask questions. Consider the example in (3).

> ok we install the extractor there's no guarantee it's   (3)
> going to keep working

Example (3) occurred in a discussion about installing a new extractor fan in a computer room. The question arose as to whether the old fan should be repaired or replaced. The first clause in (3) could be replaced by a concessive-conditional clause *even if we install the extractor*, but was in any case correctly interpreted by the hearer. Installing a new extractor was only a possible event, and the clauses *there's no guarantee it's going to work*, in spite of the present tense, only made sense if they described the situation following installation of a new fan. Using this information, the hearer correctly interpreted the speaker as conceding a point, establishing a condition, and making a statement about the situation contingent on that condition.

Important too is the extent to which speakers (and writers) use fixed expressions, that is, expressions with a relatively fixed syntax and stock of lexical items. Examples are: *Some people are hard to please*; *There's no pleasing some people*; *It's none of your business*; *Once you've done that, the rest is easy*; *I'll believe it when I see it*; *I thought you'd never ask*. Such fixed expressions or clichés are frequent and have a role to play in the first and second language learning. Of course, speakers of a given language produce and recognize combinations of syntactic units and lexical items that they have not heard or used before; but, given the exigencies of spoken language listed in Sect. 3 and the fact that speaking is often combined with other tasks, both manual and cognitive, the existence and use of fixed expressions can be seen as providing a solution to large cognitive burdens.

4.3 Constructions Typical of Written English but Rare in Spoken English

A significant number of constructions occur in (formal) written English but are rare in informal spoken English.

First, there are subordinate clauses introduced by *although, since, as*. The 100 hours of conversation described in BM contain no subordinate clauses of concession. Speakers do concede points in the course of the discussion but avoid the written construction, as in *Although she knows nothing about maths, she's a pretty good programmer*, preferring a main clause ending in *though*, as in *She's a pretty good programmer—knows nothing about maths though*. Subordinate clauses of reason introduced by *because* are relatively frequent, but there are no clauses of reason introduced by *as* or *since*. There are no subordinate clauses of purpose or result. M's corpus contains three purpose clauses, 16 result clauses, and 23 concession clauses from the working-class speakers, compared with 158 conditional clauses, 436 time clauses, and 72 place clauses. For the middle-class speakers, the numbers are, respectively, three, 28, 31, 164, 247, and 38. That is, subordinate clauses of concession, result, and purpose are infrequent even in the mature adults recorded by M and are absent from the 16-, 17-, and 18-year-olds recorded by BM.

Typical constructions in formal prose are gapping, a construction in which two clauses are combined by means of ellipsis, as in *Celia likes van Gogh, and Bill—Rembrandt*, and right-node-raising, as in *Sue likes, and Bill hates, cross-words*. Neither construction is reported by BM or M.

There are short gerunds, as in *washing dishes*, and long gerunds, as in *his washing the dishes*. Long gerunds are completely absent from AG, B and M, and short gerunds occur as complements—as in *I hate washing dishes* and *It's no bother picking you up at the station*, but never as subjects. M reports the occurrence of gerunds but does not specify their function. Infinitives are likewise very common as the complements of verbs—*He refused to work, She persuaded him to tell his parents*—but not as subjects. Examples such as *To do nothing to help strikes me as stupid* are typical of written English but are not to be found in informal spoken language.

The structure accusative + infinitive, as in *I considered her to be the best candidate*, does not occur in AG, A, or BM and is not mentioned by M.

Participial phrases do occur in noun phrases, but not in subject noun phrases, as in *It's got animals drinking at it*, or *We noticed the man sitting at the window*. Another structure, the free participial construction that modifies a clause, as in *Sitting at the window, I noticed a car at the bank* and *Covered in confusion, he apologized*, is very rare in spoken English. It is completely absent from AG and BM, and M reports an occurrence of 2.5 per 1000 words.

It does occur in A (cf. example (1) in Sect. 4.1), but it is important to note that the A corpus was provided by first-year university undergraduates, that is, by people who had reached higher education and had a good command of written English.

Certain conditional constructions occur: the usual subordinate conditional clause introduced by *if* is quite typical in spoken English (cf. subordinate clauses introduced by *although*, etc., discussed above). Completely absent from the data is the construction exemplified in *Were you to write to her, she would forgive you* and *Should you meet him, pass on my best wishes*.

The typical construction of indirect questions in written English consists of a complement clause dependent on a verb or preposition, the complement containing the indirect question. The complement has a WH word but declarative word order: compare *We asked what she had written*; *This is not just a case of whether the two words can combine*; *She raised the question of who we could persuade to take on the task*. In spoken English, the typical construction consists of a verb or preposition followed by a clause with the syntax and word order of main interrogative clauses: compare *We asked what had she written*; *This is not just a case of can the two words combine*; *She raised the question who could we persuade to take on the task*.

4.4 Relative Clauses in Spoken English

Relative clauses occur in spoken English, but their structure differs from the structure of relative clauses in written English. In the BM, AG, and A databases, they are typically introduced by *that*—as in *the student* **that** *phoned*, and definitely not *the student* **who** *phoned*. *Whom* and *whose* are completely absent, though *where* and *when* are found, as in *the place where the bridge is*. Shadow pronouns (in bold) are found, as in *the girl that* **her** *eighteenth birthday was on that day was stoned, couldnae stand up*; *the spikes that you stick in the ground and throw rings over* **them**; *an address which I hadn't stayed* **there** *for several years*. Prepositions are always at the end of relative clauses (*the shop I bought it in*) but are regularly omitted (omissions marked by the bold brackets)—*there's a rope that you can pull the seat back up* [ ]; *I haven't been to a party yet that I haven't got home* [ ] *the same night*. *That* is omitted in existential constructions—*we had this French girl* [ ] *came to stay*; *there's a man in our street* [ ] *has a Jaguar*. There are no WH infinitival relatives such as *a house in which to stay*: compare *I've got a place to start* (versus *I've got a place from which to start*).

4.5 Discourse Devices in Spoken English

Speakers combine clauses into discourses. Spoken English has a range of devices for catching the hearer's attention, putting items into prominence, or focusing sharply upon them. The devices are different from those of the standard written language: different because they belong to speech and not writing and facilitate the interpretation of evanescent utterances for the standard human listener with limited short-term memory and limited impromptu processing capacity. The devices, however, are no less subtle or consistent than the devices of standard written English.

Speakers spread information over small chunks of syntax. The spoken English in the corpus is organized in small phrases or clauses juxtaposed—that is, not integrated. Compare (4), which is an utterance produced by a participant in the Map Task describing part of the route on his map. Note that in B's utterance, the information about how to reach the waterhole is expressed by a conditional clause *if you go down*... and that the description of the waterhole is spread over four clauses (separate clauses are shown on separate lines). The paraphrase in (5) is a typical edited piece of dense written syntax packed into a single clause:

B:	right if you go from the front giraffe's foot about hold on let me see— (4)
	if you go down about—straight down about 6 cm you find the waterhole
	and it's a big hole with reeds round the side of it and animals drinking out of it
	and it's about—it's a an oval hole
	it's about 2 cm wide north to south
	and from the side to side it's about—3 cm wide ...
	It's a big oval waterhole about 2 cm wide north to south and about 3 cm wide from side to side, surrounded by reeds and with animals drinking out of it. (5)

Speakers often announce a new topic by means of a noun phrase followed by a complete clause containing a pronoun referring back to the noun phrase. This construction, exemplified in (6), is not just a device for avoiding syntactic tangles, since it occurs frequently with simple noun phrases and with no hesitations. The noun phrase may be introduced by *there's*, as in (6d).

it's not bad— ma Dad he doesn't say a lot	(6a)
—the driver he's really friendly—you get a good laugh with him	(6b)
—well another maths teacher that I dinnae get he must've corrected my papers	(6c)
—and there's one girl she's a real extrovert	(6d)

Written English possesses what are called the IT cleft and WH cleft constructions. The former, as in *It was Bill who left*, occur regularly but no frequently in informal spoken language. However, WH clefts such as *What I want is a large cup of coffee* are much rarer. Another WH cleft, as in *What he does is to interrupt at*

every turn, focuses on a verb and its modifiers and through them on an event. This construction is very rare in spoken language, but the same effect is achieved by a relatively common construction in which the *what X does* part is followed by a whole clause, as in *so what you had to do was you got a partner and you got a match...* or *but what you did in the evening you carried a sandwich or two*. The latter example does not even have *was/is*. The essential difference is that the spoken construction has two separate complete clauses—*what you had to do* + *was* + *you got a partner*, whereas the written construction has the second clause reduced and integrated with the first—*what you had to do* + *was* + *get a partner*. In contrast, WH clefts are quite frequent in questions, as in *where is it he works again?* and *who is it that's been murdered?*

Various focusing devices give prominence to items (or propositions) that the speaker wishes to introduce into the discourse. Entities deemed new to the hearer are introduced by expressions such as *can you see an X?*; *do you have an X?*; *have you got an X?*; *do you see an X? can you see a fast-flowing river?*; *do you see a lions' den?*; *have you got an abandoned cottage?*; *do you have a golf course?*. Entities deemed known to the hearer are introduced by *Can you/do you see...* but also by *you know X*, or just *know X?*, and by *You see X* (or just *see X?* in some nonstandard varieties of English): *Can you see the castle?*; *Know the bridge across the fast-flowing river?*; *(You) see the crashed plane?* (examples from the AG and A databases.)

The word 'see' can have its basic perception sense, as in *(you) see those old houses...this area was all houses like that right round*, but the connection grows more tenuous in (7), where *see* introduces a proposition. Note also the imperative use of *see* as in *see here! I've had enough of this nonsense!*

A: there's a car park   (7)
B: aye—see—I hate going in there

(You) see introduces and highlights subordinate clauses, as in *see if you go straight down—but not go straight to the aeroplane—right? see where the—see where the pilot would go—that wee bit*.

Propositions and properties are introduced by *the thing is* and *thing is*, as in *but the thing is—at our age what is there what sort of facilities can you provide* and *thing is—he's watching the man he's not watching the ball*. A prepositional phrase can be added, as in *the thing about school is that you can get them to relax*, or an adjective phrase, as in *that's the bad thing—there's always someone knocking on your door*.

New propositions or entities can be introduced and highlighted by a question uttered and answered by the speaker: *Do you know what he's just done? He's invited his sister to come and stay*, or *And who's coming to stay with us? His sister!*

Another highlighting item is *like*. It is dismissed by some analysts as a pause-filler, but has specific functions and occurs frequently where there are no pauses or hesitations. It typically highlights an item explaining a preceding piece of discourse or leading to an explanation. In interrogatives, it concentrates a request for information on a particular point.

so like you were left with three teachers
there?   (8)
[the speaker is checking on information that has already been given by the addressee]

A: we get lectures there as well I've been on a   (9)
     chemistry one
B: I've been on a chemistry one as well—that was a right bore the sex life of insects
C: really in chemistry? I thought that would be in like biology
[emphasizes contrast between biology and chemistry]
B: no it was chemistry they kept giving us all the silly formulas

A: ...sometimes I go there with my family you   (10)
     know— it's really tremendous cause—there's
     wee kiddies' pool you know where my wee girl
     can swim you know—she has her wings
     like—she jumps right in ...
[explaining that A's daughter is not really precocious, merely that she does not need to keep herself afloat]

5. Linguistics and Spoken and Written Language

Ong (1982) presents evidence that 'nonliterate folk' (his term) reason, communicate, and remember information differently from 'literate folk.' The work reported above demonstrates the distance between spoken and written English, and differences between standard and nonstandard further complicate matters. For spoken and written Russian, for example, the problems are even greater, basic constituent structure being affected along with the arrangement of clauses, types of referring expressions, and the case system, quite apart from the organization of discourse.

A number of fundamental research questions arise. Spoken language being acquired naturally, but written language being taught in schools, and the move from nonliteracy to literacy entailing large cognitive changes as argued by Ong (1982) and Goody (1977), the adequacy of theories of first language acquisition and those of language typologies is called into question. English is not classified as a language with double negation and the relative clause structure of general complementizer and shadow pronoun, yet these constructions are typical of much nonstandard-spoken and general-spoken English, respectively. One is also led to question the adequacy for spoken language of theories of constituent structure, based on edited, integrated, manipulable, written texts rather different from

loosely structured, informal, spoken texts. The problem has been noticed with respect to, for example, certain Australian aboriginal languages, which seem to lack complex constituent structure, but it has not even been addressed with respect to the spoken varieties of the major written languages. Spoken and written language is an immense topic. Its importance has gone largely unrecognized in linguistics (the Prague School are honorable exceptions) but its theoretical day approaches.

Speech Play

M. L. Apte

Since both language and play are panhuman activities, it is not surprising to find language as manifested in speech to be the object of play in most societies. Not until the nineteenth century, however, did scholars begin to regard speech play as a worthwhile topic of research. This was in keeping with the neglect of the topic of 'play' itself. Although play is one of the most common and fundamental activities not only of humans but also of many animals, it was not given serious attention by scholars.

The situation has changed, however, during the second half of the twentieth century. It has become increasingly clear to linguists, anthropologists, folklorists, historians, antiquarians, and scholars from related disciplines that play in general, and speech play in particular, is a major activity in its own right in most cultures of the world. The form, function, and sociocultural context of both structured and unstructured play have been and continue to be extensively analyzed.

1. The Concept of Play Defined

The single most influential work in the domain of play is that of Huizinga (1955). Since then, others have studied the phenomenon of play extensively, and several theories have been presented concerning the form and function of play. In 1974, scholars from various disciplines in the humanities and the social and natural sciences in the USA, who were interested in researching play, established The Association for the Study of Play (TASP). Since its inception, the association has held annual meetings, and several volumes of papers presented at these meetings have been published. The association also publishes a journal, *Play and Culture.*

In general, play is considered an activity that is carried out within the boundaries of space and time, is voluntary in nature, and is distinct by its lack of seriousness and purpose except that which arises from within its arbitrarily defined context. It is also marked by manipulation of objects, movements, and sheer creativity. The function of these activities is solely the pleasure derived from them. There is no outside reference or aim toward which it is directed. Play is most often carried out in an 'as if' reality, a second reality which is distinct from the sociocultural reality.

2. Speech Play

Speech play is a type of play in which language is the principal focus of attention. Language is manipulated in various ways as a part of the social interaction within the play frame. The purpose of engaging in such activity is entertainment, amusement, and aesthetic pleasure. Both adults and children engage in speech play. Speech play can be unstructured or structured. If the latter, it constitutes the category of games within the broad conceptual domain of play.

276

The remainder of this section indicates the scope of research carried out up to the time of writing, and more is likely to be undertaken in the future. The disciplinary and theoretical orientations of the scholars often determine which aspects of play are emphasized.

The first objective has been the identification, analysis, and description of different types of speech play in individual cultures. The main purpose is to establish some kind of typology of verbal games and unstructured speech play. In addition, the underlying patterns, conventions, formulaic rules, etc. which characterize each type of speech play are described in detail. Established types are often referred to as speech genres, and indigenous folk labels for them are identified. Research conducted during the second half of the twentieth century has resulted in the establishment of several types of speech play, such as puns, nursery rhymes, counting-out rhymes, nonsense words, limericks, riddles, ritual insults, verbal contests, mnemonic devices, and jokes, to name just a few. The broad structural characteristics of each have been identified. Such a typology is useful as an initial descriptive framework for an investigator just beginning research on speech play in a specific culture until s/he can establish the culture-specific categories.

The second objective is the description of the sociocultural contexts in which various types of speech play take place. Although speech play is generally a leisure-time activity, existing ethnographic evidence suggests that well-established genres of speech play in some cultures take place in very specific nonleisure environments. For instance, they are used in competition for selecting the most versatile, articulate, and creative individual, who thereby acquires social prestige. Occasionally, speech play is a part of religious rituals.

The third objective is the examination of the putative or actual functions served by verbal games. It is important to note that although children are thought to be the most active participants in speech play, it is not unusual in many cultures for adults also to engage in speech play.

Cross-cultural comparison of speech play is the fourth objective, in order to discover which types have a wide distribution reflecting panhuman patterns and universal human tendencies. For example, it can be assumed that punning occurs in all cultures. Similarities and differences in form and content of various types of speech play need to be investigated, and cross-cultural variations need to be explained. For example, the riddle may be a universal category, but the structure, rules, and sociocultural contexts of riddles may differ across cultures.

The final objective has been to evaluate the relevance and effectiveness of theories for explaining the universal and culture-specific nature of speech play and its place in the sociocultural system as a whole. New theories need to be developed if the existing ones appear unsatisfactory for explaining the forms and functions of speech play within a universal framework or for accounting for cross-cultural variation.

There is extensive ethnographic literature describing and analyzing speech play in many cultures. Many ethnographic studies have focused on specific types of speech play. For instance, there is extensive literature on puns, riddles, tongue-twisters, nonsense words, secret languages, counting games, ritual insults, jokes, and verbal duels (see the bibliography in Kirshenblatt-Gimblett 1976). Whether or not these genres are to be considered universal categories is a moot issue.

3. Linguistic Characteristics of Speech Play

Since speech play involves the use of language in innovative ways for amusement, there is no limit to the kinds of games that can be invented. It appears that all structural elements and domains of language can be and are involved in speech play. For example, the label 'tongue-twisters' is used to describe speech play that is typically based on the difficulties of articulation when a sentence having several similar speech sounds is uttered rapidly. For example, the English sentence *She sits and shells, she shells and sits* is a tongue-twister, since it contains the consonants [s] and [ʃ], which are similar and which appear in close proximity in succession. The virtuoso performance involves repeating such a sentence rapidly and correctly. If mistakes in such a performance result in the sentence becoming obscene and/or scatological, it is considered even more amusing. Anyone trying to utter the above example rapidly can quickly find out what happens.

Another type of speech play involves inventing utterances that sound the same when recited forward and backward. The Marathi-speaking children in India show off by reciting such utterances as [cimā kāy kāmācī] 'What use is Chima [proper name of a female] for work?' and [to gajānana jāgto] 'That Gajanan [proper name of a male] stays awake' in which the sequences of syllables sound the same forward and backward. Such structural play is based on language-specific phonotactic constraints, and the existing permissible phonological sequences are exploited for novel creations.

Secret and/or play languages are created by changing the phonological structure of words in utterances. The most commonly employed mechanisms for developing such languages are addition, subtraction, reversal, and substitution. Pig Latin is probably the best-known secret language among English-speaking children. The utterances in it are created by phonological transformation of the first phoneme of each word to the end of it and then

tacking on the vowel glide /ey/. Thus an English sentence *He does not know it* becomes *ehay oesday otnay owknay itay*.

Such secret and/or play languages have been described from many cultures. Among the Cuna Indian children of Panama, there exist several play languages which have been analyzed by Sherzer (1976), who has also presented French and Javanese play languages. One interesting aspect of the play languages which Sherzer described was that they were all derived from extremely colloquial speech varieties among the respective linguistic communities. The novel creations resulting from the various mechanisms mentioned above do not always have to be meaningful for sheer aural pleasure. Very young children often string together sounds of their language in an arbitrary way, creating nonsense words, and can actually converse with other children until they all end up giggling.

Speech play is also based on morphology. Children often create new words using various affixes. They also enjoy combining words in unusual ways. Creating the longest words or creating utterances which are alliterative are some of the common games that children engage in.

Semantics is the basis of much speech play. Puns are based on exploiting the relationship between form and meaning. A word or a phrase is used in discourse in such a way that the primary or literal meaning gives way to metaphorical and/or secondary meaning. Many children's riddles are based on such punning. For example, note the following riddle:

Question: Who crosses the river twice and is still not clean?
Answer: A dirty double-crosser.

Puns occur not only in the speech of children but also in that of adults. Some adults seem particularly prone to punning, which has been both highly praised and strongly criticized. For some, punning reflects an intellectual skill, while for others it is the lowest type of humor. Redfern (1984) takes the view that the pun has been given a bad name without justification. There is extensive literature on the nature and function of puns, including interlingual puns.

Whether mistakes committed in linguistic performance can be considered speech play or not is debatable. The intention of the speaker is a crucial criterion in such determination. For example, the most commonly found types of inadequate linguistic performance are spoonerisms and malapropisms. In a spoonerism, transposition of linguistic units such as phonemes, syllables, morphemes, words, or phrases occurs in an utterance, thereby resulting in a different one often unintended by the speaker. William Spooner, the dean and warden of New College in Oxford, from whose name the label is supposed to

have been derived, was well known for such utterances. For example, among the popular spoonerisms associated with him are *noble tons of soil, You have hissed all my mystery lectures*, and *You have tasted the whole worm*. It is doubtful that Spooner was deliberately engaging in speech play when he uttered these sentences.

Similarly, a malapropism is defined as 'ridiculous misuse of a word in place of one it resembles in sound, especially when the speaker is seeking a more elevated or technical style than is his wont and the blunder destroys the intended effect' (Hockett 1967: 927). The term is derived from the fictional character Mrs Malaprop, to whom is attributed the following utterance: *If I reprehend anything in this world, it is the use of my oracular tongue, and a nice derangement of epitaphs* (Nash 1985: 149). In the occurrence of malapropisms, the speaker is not even aware of the fact that s/he has committed an error. Thus, while from the listener's viewpoint such errors may be mirth-evoking, they cannot be described as speech play since such may not be the intention of the speaker.

4. Speech Play and Performance

Since verbal interaction is an inevitable aspect of social interaction, it is not surprising that speech play is a social phenomenon. As such, those who are skillful at displaying their virtuosity are often in demand and achieve prestige and status by their display. In many cultures, such performance becomes part of a competitive interaction. The most stylized forms of speech play involving such competition are ritual insults and verbal duels, which occur in many societies. For example, they are popular among African-American boys and girls, Turkish boys, Samoan children, and children and adults among the Chamula Indians in Mexico, and they have been analyzed (see also *Verbal Duel*).

While the use of language in everyday social interaction is rarely labeled as performance in common parlance, there are well-established conventions for performances of music, dance, and drama. In theater, comedies use speech play extensively, and spectators who watch them have a full expectation of deriving pleasure from such a display by various characters. The performative aspect of speech play becomes important in the proper execution of conventions established for different genres of speech play.

Although during the early period of language acquisition children go through several stages of spontaneous, unstructured speech play, they increasingly learn various types of structured speech play which often take the forms of linguistic games. Children also learn and memorize from their peers many ready-made examples of such genres of speech play as rhymes, jokes, taunts, insults, and riddles.

Linguistic games have established rules which the children learn from their older siblings and more experienced peers, since knowledge of the rules is a prerequisite for participation in these games. Some children even become very adept at exploiting the existing rules for their personal benefit (Goldstein 1971). Some are also better at playing these games than others. What is important is that all participants know the rules of whatever games are being played, so that nonconformity is not tolerated. Therefore, structured speech play assists in the process of socialization.

5. Speech Play and Verbal Art

The views in the existing literature concerning the difference between these two concepts are not clear-cut. Sanches and Kirshenblatt-Gimblett (1976) claim that in speech play there is more emphasis on the process itself, in contrast to verbal art, which focuses on the form rather than the content. They also claim that the concept of verbal art is more appropriate to adult activity involving speech performance, since children are not aware of the notion of art, and that children are engaged in speech play activity as an end in itself. Despite these and other attempts to separate speech play and verbal art, the fact remains that they overlap considerably, and only contextual factors can determine whether or not a given occurrence of verbal performance can be labeled as speech play or verbal art.

6. Speech Play and Humor

The nature of the relationship between humor and speech play is complex and multifaceted. Since both frequently lead to a mirthful state of mind, and since both focus extensively on language, there is much overlap. Another similarity is that both are culturally conditioned. Many humor genres can also be considered as types of speech play (Esar 1952). For example, riddle and pun are humor genres as well as types of speech play. Both are based on performance, innovative ability, and creativity, and have fixed structures.

Only linguistic games which involve competition can be said to be devoid of humor. This is true only for the contestants, however. The spectators of verbal duels and/or ritual insults and other types of competitive speech play are not concerned with who wins but are keen on enjoying the entertainment and amusement provided by them. It is, therefore, almost impossible to list criteria that can be uniformly applied to separate humor from speech play. Whether a particular verbal performance is an example of speech play or of humor or of both can only be contextually determined. For the most part, its allocation to one or the other category may be somewhat arbitrary.

7. Speech Play and Cognitive, Linguistic, and Sociocultural Development Among Children

Children in all societies and cultures learn language as an essential part of their enculturation and socialization process. One significant way in which children learn to master the language of their community is speech play. Many types of speech play, such as riddles, jokes, play languages, and counting-out rhymes, facilitate children's cognitive development. They also contribute to children's social development by enabling them to gain experience of how to plan strategies, how to put on public performances, and how to deal with interrogation, ambiguity, and humiliation. Speech play is thus important in children's understanding of the nature of social relationships and their place in them. Children engage not only in manipulating the structure of the language in their speech play, but also in mimicking the speech of adults by pretending to act out various social roles in their play activities. Thus, speech play assists considerably in children's mastery of both the structure of language and its culturally appropriate use.

Style

M. Short

The most commonsensical understanding of the meaning of the word 'style' is that it relates to the typical way(s) in which one or more people do a particular thing. Thus, eating one's food slowly, chewing each mouthful 50 times with one's mouth closed constitutes a different style of eating when compared with someone who eats quickly, hardly chewing the food at all. As Ohmann (1964) puts it, style is a *way* of doing *it*. Style in language behavior thus becomes alternative ways of expressing the same content. This commonsense starting point will be used for this discussion of style.

1. Style as Linguistic Choice

It should be clear that style in the sense outlined above can only exist if there is more than one way of saying or doing the same thing. Hence, substituting a *b* for a *p* before *-in* does *not* constitute a phonetic *style* choice because the two different results, *bin* and *pin*, have different contents. Saying *bin* in a gravelly voice on the one hand, or a squeaky voice on the other, could be a style marker. The equivalent of this kind of distinction at a lexical level can be seen when comparing (a) *He mounted his horse* with (b) *He mounted his bicycle* and (c) *He mounted his steed*. The change of noun from *horse* to *bicycle* involves reference to a different entity in the word, and so (a) and (b) are not two ways of saying the same thing, but descriptions of two different actions. On the other hand, replacing *horse* with *steed* or *nag* (see (a) and (c) above) can be said to constitute a style choice because the resulting sentences can be seen as alternative ways of describing the same action. It is from this kind of observation that it has been noted that style can be construed as linguistic choice (cf. Enkvist 1964, 1986, Halliday 1971), although, given the above discussion of *bin* and *pin*, and *horse* and *bicycle*, it would be more accurate to say that linguistic choice is a necessary but not a sufficient condition for the existence of style in language. As linguistic choice can occur at any linguistic level, it will be clear that particular styles may result from choices made at any linguistic level or combination of levels.

In particular linguistic contexts, however, choices apparently made possible by the language system will not necessarily be available, as Fowler (1972) makes clear. Consider the two sentence *She called him* and *He was called by her*. The active sentence and its passive reformulation would appear to be two equivalent syntactic ways of expressing the same content. But, with different preceding linguistic contexts, the apparently free choice disappears. The first of the above two sentences appears more or less obligatory when preceded by *And then you'll never believe what the rat did next ...* , while the second is demanded by a preceding sentence like *And that wasn't all that happened to her*. In essence, what happens here is that other, more important considerations make an apparently free choice obligatory. In this case, given/new relations in the information structure of the sentences are paramount. But a whole range of considerations are almost certainly involved, for example, the avoidance of ambiguity or inelegance. So, *He looked the book up* has *He looked up the book* as an alternative. But if the beginning of the sentence in which the clause appears is *He looked up the stairs and then ...* , the second of the above two choices is unlikely because it predisposes the hearer/reader toward an interpretation where the subject of the sentence peers along the book's cover, from top to bottom, rather than consulting a library catalog. On the other hand, *He looked up the book upstairs* is much more likely than *He looked the book up upstairs*, at least in written English, because it avoids inelegant immediate repetition of *up*. Hence, what constitutes linguistic choice is not always as straightforward a matter as it might at first seem.

280

In looking thus at possibilities of style choice within the boundaries of the system of rules which constitutes the English language, it is clear that an understanding of style must involve comparisons between what actually occurs and what might have occurred. But it is also worth noting that writers can make *deviant* choices, that is, choices which fall outside the normal bounds of English. Such choices may affect style and/or meaning (Enkvist 1964, 1973: 98–108, 1986). If a modern writer wants to give his writing a highly 'poetic' style, for example, he might well choose archaic words (e.g., *haycock*) and structures (e.g., adjective after, instead of before, the noun—*haycocks dry*). A novelist might choose a much more informal language for his narrations than is conventional (e.g., Mark Twain, J. D. Salinger, Alan Sillitoe), thus giving his writing a characteristic style by deviating from the assumed norms for the novel. Some writers (e.g., the poet E. E. Cummings) have created characteristic writing styles by deviating from the grammatical, semantic, and orthographical norms of English in very dramatic ways.

It will be clear from the foregoing that a consideration of style must in some sense be comparative. At a microlevel, one compares what occurs with other choices which might have been made within or outside the language system to express roughly the same content. This comparative aspect does not, however, have to be conducted in such a restricted way. For example, it is possible for someone to talk about Conrad's style as opposed to that of James or Lawrence, in spite of the fact that the contents expressed are unlikely to be equivalent. Indeed, to find two writers producing different versions of the same content is comparatively rare (but compare parodies and rewritings, for example, Twain's rewriting of a piece by James Fenimore Cooper, see Hendricks 1976: 183–210). For styles to be established irrespective of content, regularity of choice with respect to particular style features becomes paramount.

2. Style and Iterativity

For a style to exist, the same sort of linguistic choice must be repeated on a reasonably consistent, iterative basis. One of the style features commonly thought to be characteristic of the language of science, for example, is the regular use of passive constructions with deleted agents (e.g., 'the copper sulfate was placed in the test-tube'). This does not mean that other kinds of writers do not use this construction, or indeed that scientists always use passives with agent-deletion in preference to active constructions or passives without agent-deletion. Instead, a statistical assumption is being made to the effect that, all other things being equal, scientific writing will display a significantly higher use of this construction than, say, romantic fiction. This statistical basis for style is

made clear in Leech and Short (1981: 42–73). But the issues concerning what is to be counted, how big differences between two writers have to be in order to be significant, and so on, are both complex and technical (see, for example, Doležel and Bailey 1969, Morton 1978), and many analysts and students of language and literature have shied away from taking the study of style to its ultimate, quantified conclusion because they feel either that the work needed does not justify the effort expended, or that such a 'mathematical' approach is unsuited to the humanist discussion of literature. A further issue, which is by no means fully understood, is the way in which linguistic structure, including structural iteration, interacts with context and with expectations on the part of the reader or hearer. Because people expect to find passives in scientific writing, or abstract nouns in the prose of Henry James, they are likely to respond more to such entities when coming across them in these contexts than in other texts, even if those other texts contain a higher proportion of the features concerned. At the end of the day, however, style must have some quantitative basis.

3. 'Style = Content' versus 'Style = Meaning'

This discussion of style began with the familiar notion that a style is a particular *way* of doing *it*. This way of looking at style, what is left after content is removed, is a longstanding one, going back at least to Aristotle's *Poetics*, and having many elegant proponents, including Pope (in *Essay on Criticism*):

> True wit is nature to advantage dressed,
> What oft was thought but ne'er so well expressed.

The most prominent view of style in the twentieth century, however, has appeared to contradict the traditional, commonsense account, by suggesting an equivalence between style and meaning. This view notes that there are no complete synonyms in language, that *horse, steed*, and *nag*, for example, do not mean exactly the same thing, and that the same can be said of the use of alternative grammatical constructions, like active and passive, which, at the very least, change given/new relations and the weighting of words in sentences. It has also been claimed that changing even apparently minor aspects of a text's linguistic structure may change its meaning. This is particularly true of short texts, like lyric poems.

This apparent bind, where style at the same time is and is not a bearer of meaning, is not easily escaped. The clue is in the exact words that the proponents of the different accounts use. On the one hand, style is separable from 'content.' On the other hand, it is not separable from 'meaning.' 'Meaning' is a much wider concept than 'content,' including content and other things besides, like connotation and significance. Leech and Short (1981: 19) argue that writers have

choices both at the level of content (what to represent) and in terms of how that content is expressed, that is, style. But style choices can themselves still be meaningful in the widest sense of the term.

Since the 1960s, there has been a tendency to equate particular views of style with particular models of grammar and their proponents, as the title to Hendricks (1976), *Grammars of Style and Styles of Grammar*, makes manifest. So, Richard Ohmann (1964), working within an early version of the transformational–generative paradigm, has used the deep structure/surface structure distinction to articulate the content/form distinction, whereas Halliday (1971), using his systemic grammar, which admits no such binary distinctions as deep and surface structure, has been a proponent of the 'style = meaning' school. But it should be clear that although the structures of these two different systems of grammatical description tend to lead their proponents toward different characterizations of style, there is no *necessary* relationship between a particular grammatical account of language and a particular view of style. For example, the idea that different transformational derivational histories had no effect whatever on meaning has been clearly abandoned by transformational grammarians.

4. The Domain of Style

Style is most often discussed in the context of literary studies. This is not surprising, as western culture has tended to study literary writing more than any other form of language. But it should be clear that any person's reasonably consistent linguistic behavior could be said to constitute a style, whether it is spoken or written, or whether the language producer is deemed to be a literary figure or not. Different weather forecasters on the television have characteristically different ways of expressing the same information, different politicians typically give their speeches with different styles, and newspaper columnists also have different styles.

Although style is most often discussed with respect to some individual writer, the domain of style does not have to be that of an individual. There can also be what Hendricks (1976: 101–72) calls group styles. Hence, a group of writers with the same outlook, or coming from the same period of time, might well share a group style. Thus, one can talk of a gothic style or even an eighteenth-century style within discussion of the novel. For discussions of nonliterary group styles, see Crystal and Davy (1969), Huddleston (1971), and Todd and O'Donnell (1980). Within literary studies, most detailed discussions of style tend to concentrate on the domain of the individual writer.

5. Authorial Style and Text Style

If one examines the apparently simple notion of authorial style characterized by Buffon's famous phrase '*style, c'est l'homme même*' (see Ullmann 1973: 64–92), it can be seen that even in this domain there are at least two notions of style being used. The first amounts to the writing equivalent of an author's fingerprints, and is seen almost exclusively in studies trying to resolve authorship. There has been a long-running dispute over the authorship of some works traditionally attributed to Shakespeare, and there are similar debates over the authorship of some of the *Spectator* papers, and, in the USA, the *Federalist* papers. Representative examples of authorship studies are Francis (1966) and Morton (1978). In this sort of study, the items counted tend to be extremely frequent and as devoid of meaning as any linguistic items can be, for example, average word and sentence length, or the repetition rate per 1000 words for so-called grammatical words like 'and' or 'of,' because such differences among writers are least likely to be affected by changes in the topic or viewpoint.

The second version of authorial style is more recognizable to students of literature. This is when they characterize someone's writing as loose, copious, tight, abstract, baroque, and so on. In this case, statements about general characteristic beliefs of the writer concerned and his view of the world are often allied to the observed style characterizations. For this kind of authorial style, the items counted typically have rather more content, for example, abstract versus concrete nouns, or dynamic versus stative verbs. Typical examples of works of this kind of style study are Milic (1966, 1971) and Ohmann (1964). This understanding of style is coterminous with the notion of 'mind-style' related to authors, and of course it can also be associated with narrators and characters. It should be clear that what has been said about authorial style above applies equally to group styles.

Finally, many scholars try to characterize what might be called text style. In this case, the items examined are likely to be even more integrally connected with meaning. Examples would be Nash (1982) and Carter (1982). Leech and Short (1981: chap. 3) combine a comparative study of the second kind of authorial style with text style analysis. The fact that this is possible indicates that text style and the two kinds of authorial style outlined in this section are best seen not as mutually exclusive, but as different, partially overlapping sections of a continuum from finger-printing at one end to text style at the other. It also helps to explain some of the confusion surrounding the term 'stylistics,' which at first sight looks as if it should be used to denote the study of authorial and group style, in spite of the fact that most proponents of stylistics concentrate on the relationship between linguistic structure and textual meaning.

It should also be stressed that a text does not need to keep consistently to one style. Indeed, style variation within some text is invariably perceived by readers as significant and hence meaningful, as a consequence of the process of internal deviation. Adamson (1989) and Trengove (1989) discuss style variation within literary texts, and Fairclough (1988) examines such variation in a Barclaycard advertisement.

Discussion of style variation within literary texts has in a sense reintroduced the issue of the domain of style. In order for styles and changes of style to be significant within literary texts, they must be correlatable with style choices made in the language as a whole. A switch from travelog-like description to legal language in a novel by Dickens can only be understood if the reader can recognize such styles, or 'languages,' outside the novel. What is true of style features related to subject matter and domain is also true of features like formality. The traditional literary discussion of high, middle, and low styles presupposed the existence (which continues) of formality-related styles which speakers of a language switch among, independent of subject matter, either to conform to particular social norms (coffee-bar talk is more informal than debates in the House of Commons), or to produce unexpected and meaningful effects by departing from those norms in an obvious way.

Taboo Words

M. L. Apte

The word 'taboo' (also spelled 'tabu') was introduced into English from Polynesian cultures where it played a significant part in the religious belief systems. The concept of taboo has been discussed in the writings of the anthropologists Frazer, Van Gennep, Wundt, Radcliffe-Brown, and Mead. Freud has also discussed it extensively in his book *Totem and Taboo*.

Steiner (1967) provides the full history of the origin of the word, its various cognates and their meanings in Polynesian languages, its significance and functions in the religious belief systems of Polynesian cultures, and its relevance to anthropological and psychoanalytic theories. Under the entry 'Tabu' in the *Encyclopedia of Social Sciences*, Margaret Mead

(1937: 502–5) defined the concept as 'a negative sanction whose infringement results in an automatic penalty without human or superhuman mediation.' According to her, one of the several meanings of the Polynesian concept of taboo is 'any prohibitions which carry no penalties beyond the anxiety and embarrassment arising from a breach of strongly entrenched custom' (quoted in Steiner 1967: 143).

1. Taboo Words Defined

The primary semantic attribute of the concept of taboo in English seems to be the same as the meaning by Mead quoted above. Prohibition or avoidance is socially determined and its breach results in anxiety, embarrassment, and public shame. This seems to be the primary aspect of the notion of linguistic taboo. Taboo words are those that are to be avoided because they are deemed unfit for normal linguistic usage and by community consensus are banned in everyday language in the public domain. In Webster's *Ninth New Collegiate Dictionary* (1990) the second meaning of taboo as an adjective is 'banned on grounds of morality or taste.' As a noun its secondary meaning is 'a prohibition imposed by social custom or as a protective measure' and as a verb 'to avoid or ban as taboo.'

Much of the discussion of taboo words in popular and scholarly literature has been based on the assumption that certain words are offending, dangerous, or sacred. Thus, underlying the avoidance of taboo words are cultural values and belief systems according to which attitudes are formed and judgments are made regarding the offending, dangerous, or sacred nature of certain words. Since there are cross-cultural variations in attitudes and belief systems, there are also differences concerning the semantic range and topical nature of taboo words. Despite such differences, it appears that in many societies words pertaining to objects, actions, and phenomena within the following domains are considered taboo.

In general, words referring to processes and states of human biological existence appear to be taboo because of their association with danger and their anxiety-provoking nature. Words referring to birth, death, pregnancy, various illnesses and diseases, menstruation, sexual and excretary activities, feces, urine, blood, and semen are considered taboo in many societies. Another taboo domain is that of deceased persons, animals considered to have special powers, ancestors, and benevolent and malevolent supernatural beings and their activities. In many cultures, referring to dead persons, sacred objects, and animals and deities is considered taboo except when done by those endowed with special powers in situations of ritual significance.

One underlying belief regarding taboo words is the magical power of the spoken word. It is as if uttering a taboo word may bring about the occurrence of the object, action, or phenomenon it refers to. Words that refer to supernatural beings are also taboo because they, too, can invoke dangerous phenomena beyond the control of human beings. Taboo words are to be avoided because they are powerful and cause unforeseen consequences. It needs to be noted that there are degrees of tabooness and some words are much more strongly tabooed than others.

Whatever the taboo words, all societies have ways of obliquely expressing their meanings using paraphrases, synonyms, euphemisms, and code words. These linguistic processes are universal. In English, for example, many speakers will use the expression 'to pass away' instead of 'to die,' or instead of saying that a woman is pregnant an expression such as 'she is carrying' is used. Use of code words is quite common. Some are phonetically similar to the taboo words, e.g., 'shoot' for 'shit' or 'fudge' for 'fuck' or they are phonetically similar nonsense syllables, e.g., 'frig' for 'fuck,' 'heck' for 'hell.' Occasionally, abbreviations are also used, e.g., 's.o.b.' for 'son of a bitch' (Saporta 1988–9: 164–5). In English language cartoons in the USA, the established convention to indicate a character's use of taboo words is to use punctuation and diacritical marks as well as other symbols commonly found on typewriter keys, e.g., '!?#%@.'

2. Other Related Concepts and Words

Terms such as 'swear words,' 'curse words,' 'obscene words,' 'four-letter words,' and 'dirty words' are often used interchangeably with the expression 'taboo words' in popular and scholarly writings. Although avoidance or prohibition is the semantic attribute shared by all of them, the range of each is slightly different. Swear and/or curse words are those which invoke damnation, misfortune or degradation of the targeted person or object. Swearing and/or cursing reflect a speaker's wrath or frustration towards a person or an object. In English 'hell,' 'damn,' 'Jesus,' and 'Christ' are commonly used curse words and 'damn it,' 'God damn it,' 'damn you,' and 'go to hell' are frequently used swearing/cursing expressions. Swearing and cursing are thus ways of venting a strong emotion.

Defining the semantic range of obscene words is difficult because notions of obscenity vary across cultures, over a period of time within a culture, and from one person to another. It appears that words that refer to sexual organs and acts are obscene. Words referring to the same organs and activity in physicians' usage and in scientific writings, however, are not considered obscene. Words that refer to the various body elimination processes and excretary substances—'shit' is the most commonly used word—are also considered by many to be obscene though they are generally labeled 'scatological' in

scholarly writing. The use of obscene and scatological words evokes disgust or repugnance in many listeners. In this respect obscenity is determined by the hearer of a linguistic utterance, in contrast to tabooness which is determined by the speaker. It is the hearer who is affected by obscene words while it is the speaker who decides which words are to be avoided because s/he considers them taboo. Not all taboo words are obscene from a speaker's point of view. Obscene words and phrases are also used for swearing and thus can belong to the category of swearing/cursing expressions. In English, a common swearing expression, for example, is 'fuck you.'

The expression 'four-letter words' is restricted because it is language specific. It is valid only for English in which many so-called obscene words, e.g., 'cock,' 'cunt,' 'fuck,' 'ball,' and 'shit' have only four letters in their spelling. It is quite possible that comparable words in other languages may also be spelled or written with four characters. No systematic comparative linguistic studies focusing on this issue exist.

The label 'dirty words' indicates a very personal and subjective attitude. For many individuals dirty words are those that refer to sexual organs and acts, body elimination processes such as defecation and urination, and excretary substances. In cultures where such acts are considered defiling and where an attitude of repugnance towards them exists, the mere use of such words arouses a strong reaction of disgust.

Whether or not a word used in speech belongs to any of the above categories depends on the sociocultural context. Generally, the use of taboo, obscene, swear/curse, four-letter, and dirty words is determined on the basis of whether the situation falls in the public or the private domain and whether the linguistic discourse is formal or informal. Words designated by any of the above labels are usually avoided in formal language in the public domain. The greater the aura of respectability in any social situation, the stricter the ban on using words that may be viewed as even mildly taboo. On the other hand, taboo words are likely to be used in social interactions among friends in a private domain where an informal speech style prevails. The use of slang among members of a close-knit group encourages the use of taboo words. According to popular belief persons in certain occupations such as the army, the navy, or construction work tend to use taboo words frequently. Their speech is considered 'colorful' by some (see also *Verbal Duel; Slang: Sociology*).

3. Cross-cultural Differences in Attitudes Towards Taboo Words

The domain of taboo words varies cross-culturally. The inclusion of vocabulary items for particular phenomena, acts, objects, etc., in the taboo word category depends on sociocultural values and attitudes. It can be hypothesized that in societies where sexual and excretary acts are generally accepted as necessary and natural, and attitudes towards them are casual and/or relaxed, there is less likelihood that words referring to sexual and excretory organs and acts will be treated as taboo. On the other hand, in societies with attitudes of disgust or repugnance towards sexual and excretary organs and acts, there is greater likelihood that words referring to them will be considered taboo.

Even in individual cultures attitudes towards sexual and excretary acts are likely to change over a period of time so that words once considered taboo may be used in speech. In nineteenth-century England and America, the puritanical ethics of communities and society at large resulted in an almost total ban on using words that referred to sexual and excretary organs, acts, and bodily excretions. Until the 1960s, these words were not used in print in the USA. In their place only the first letter, an empty space, or dashes were used. Even with liberalized attitudes, in the USA and other English-speaking communities from the mid-1960s onward, sexual and scatological words do not routinely occur in newspapers and magazines though they are now used in fictional writing. In a mass medium such as television, taboo, obscene, and swear/curse words are still not used. If they occur in real-life interview situations, they are beeped out. In the published transcripts of the taped conversations between US president Richard Nixon and his White House associates, which were full of taboo and obscene words, the expression 'expletives deleted' was used rather than the verbatim conversations.

To a large extent the sociocultural context of speech and the backgrounds of the participants in social interaction determine the use of taboo words. Such factors as enculturation and socialization, age, gender, social status, degree of religiocity, and educational level influence the use of taboo words in speech. Children and adults in agricultural rural communities have many opportunities of observing animal sexual behavior. Children growing up in poor families who lack privacy because of limited living space have many occasions to observe adult sexual activities. In such an environment references to sexual and excretory organs and activities may be common and casual. No sense of disgust or repugnance may be associated with the use of taboo or obscene words. On the other hand, a rural community may be strongly religious and hence is likely to avoid using blasphemous and swear/curse words. Much depends upon the socialization and enculturation processes which determine an individual's attitude regarding the taboo quality of words. An individual brought up in a religious and orthodox household with puritanical values is likely

to consider many more words taboo than one brought up in a nonreligious atmosphere which may treat body-waste elimination processes and sexual and procreation acts as natural, not shameful or repugnant. Therefore, even within a specific culture, words that may be shocking to one individual and/or a particular group of people may not necessarily be so to others of a different background.

In general it appears that women, old persons, educated individuals, urbanities, and elites are less likely to use taboo, obscene, and swear words in public domains than men, young people, uneducated persons, rural folk, and the proletariat. Cultural notions of modesty and politeness often constrain individuals, especially women, from using taboo words in the public domain. In many societies such language is not permitted in social settings where both men and women are present.

Although women generally abstain from using taboo words in the public domain, in some cultures old women beyond menopause are known to compete with men in freely using such words (Apte 1985: 79–80). Even those who normally avoid taboo words in their routine use of language are given to using them on special occasions such as specific festivals and rituals. There is ethnographic evidence which indicates that in many societies saturnalian celebrations create an atmosphere where the use of taboo words and lewd and lascivious behavior on the part of participants is quite common. Such occasions have been labeled 'Rites of Reversal' (Apte 1985: 152–3).

4. Functions of and Responses to Taboo Words

The use of taboo words is generally associated with strong emotions. Therefore, speakers use them to express strong feelings and listeners respond with equally strong feelings and reactions. Speakers who are aware of the potential of taboo words to arouse strong reactions may deliberately use them to shock their listeners. The use of taboo words gives an individual a feeling of momentary freedom from social conventions and constraints. Individuals may also use taboo words as a protest against what they consider antiquated values regarding speech because using these words will make their listeners uncomfortable. The use of taboo words in such a context can also be considered a form of verbal aggression since those who believe in avoiding such words in their speech will be forced to hear them. In a way, then, one function of taboo words is to degrade listeners, especially women who are much less likely to use them because of the ideas of modesty that dominate women's actions and speech in many cultures (Apte 1985: 74–5). For the same reason the use of taboo words is common in ethnic slurs since such words reflect the strong aggressive and hostile

feelings a speaker may have towards certain ethnic groups. Their use is meant to insult and offend the targeted group.

In some contexts the use of taboo and obscene words may serve an opposite function, namely to show affection. Verbal encounters among close friends may be full of taboo and obscene words as terms of endearment (Bloomfield 1933: 155, 401, Cameron 1969: 101) and occasionally may even be accompanied by insults and horseplay, all of which is seen as joking. This usually results in loud laughter (Apte 1985: 259).

Individuals may use taboo words to express pent-up emotions such as anger or frustration. Persons who have occupations that are stressful also tend to use taboo words since using them relieves tension. Anthropologist W. W. Pilcher (1972) who studied a community of longshoremen in the city of Portland, Oregon, USA, observed that there was a high degree of taboo word use among these men when they were working on board the ship since such work was quite hazardous and stressful. Once they were off the ship and engaged in leisure activities, the use of taboo words declined significantly. The longshoremen were also very careful in totally avoiding swearing, obscenities, and the use of taboo words in family surroundings.

The repeated use of taboo words diminishes their tabooness since the prohibition on their use is the crucial attribute of such a designation. Individuals who use taboo words excessively in their speech may become insensitive to both the socially determined taboo nature of these words and the fact that such words are offensive to listeners. Individuals known for their excessive use of taboo words may be avoided by others who do not wish to be offended.

5. Taboo Words and Linguistic Differentiation and Change

Linguistic research has shown that in many societies the speech of men and women differs and that the degree of such difference can vary from one society to another. One explanation put forward for this is that the phenomenon of taboo causes these gender speech-differences since men in many linguistic communities use words in several contexts that woman never use. However, linguistic differences attributed to gender differences occur not only with regard to vocabulary, but also with regard to phonology, morphology, and syntax (Trudgill 1983: 78–99). The extensive research done on the topic of language and gender (see references in McConnell-Ginet 1988) since the mid-1970s reflects the complexity of the problem.

To what extent language change is due to the existence of taboo words has not been systematically

investigated. It is common for speakers of a language to avoid not only taboo words but other phonetically similar words which consequently may fall out of use and become extinct. An explanation for the replacement of the old word 'coney' (pronounced [kʌni]) by the word 'rabbit' is that the former sounds very similar to a taboo word (Trudgill 1983: 31). No quantitative studies exist, however, to test such a hypothesis.

The Internet and Language
C. Thurlow

Weblish, netlingo, e-talk, tech-speak, wired-style, geek-speak, netspeak, and so on are all terms used popularly to describe the sort of language and communication in the different channels (or 'niches') of the internet (or net): emails, chatrooms, bulletin boards, newsgroups, websites, and 'virtual worlds.' As a subfield of Computer-Mediated Communication (CMC), what interests sociolinguists most about language on the internet are the particular forms and functions of *netlingo* or *netspeak*, and whether they are sufficiently different from other varieties of language to justify such distinctive labels.

1. Mapping the Potential Field

In spite of increasingly widespread usage, there is still only a modest literature on the sociolinguistics of the internet; nevertheless, interest in language and the internet may be divided loosely into five interrelated themes:

   (a) *multilingualism* (e.g., the prevalence and status of different languages on the internet);

   (b) *language change* (e.g., lexical, syntactic, grammatical, stylistic, and other linguistic changes over time);

   (c) *conversation/discourse* (e.g., changing patterns of social interaction and communicative practice);

   (d) *stylistic diffusion* (e.g., the spread of internet jargon and linguistic forms into general usage);

   (e) *metalanguage and folklinguistics* (e.g., the way these linguistic forms and changes are labeled and discussed).

2. The Contexts of Computer-mediated Communication (CMC)

There is no homogenous speech community on the internet; equally there is no single language of the internet. New ways of communicating on the internet are evolving and emerging all the time in response to technological and social changes. As research shows, any evaluation of language and communication on

287

the internet therefore needs to take certain contextual factors into account, for example:

    (a) the format and type of channel (e.g., email or webpages);

    (b) the participants (e.g., male or female, young or old);

    (c) the length and nature of their relationship (e.g., long-term or fleeting, personal or business);

    (d) the topic and purpose of the exchange (e.g., medical advice or romantic date);

    (e) the general attitude of participants towards communication on the internet (e.g., enthusiastic or skeptical); and,

    (f) whether interaction is asynchronous (i.e., not in real-time) or synchronous (i.e., in real-time).

3. Multilingualism: The Languages of the Internet

The tendency when speaking of netlingo has been to assume—rightly or wrongly—that it is necessarily a variety of English. While the proportion of English used on the internet remains considerably high, figures supplied by organizations such as *Cyberatlas* confirm the diminishing influence of English. (English-speaking internet users: 1996—80 percent, 2000—50 percent, 2005—30 percent.) The dominance of English as the language of the net will inevitably be diminished by the rise of other languages (especially Chinese), not least in the face of increasing commercialization which demands an attention to niche markets.

4. Language Change: Writing That Looks Like Speech?

Influenced by the physical constraints of the technology itself (e.g., typed text) and shifting social-economic priorities (e.g., globalization), *netlingo* emerges from the coinages, jargon, and communicative practices of those specialist groups (e.g., computer *geeks* and *hackers*) driving the development of communication technologies.

The emphasis in *netlingo* is on a mixture of speed, efficiency, informality, and creative typography whereby many of the traditional rules of grammar and style are subverted. To this end, *netlingo* relies principally on expression which is QWERTY-driven (i.e., whatever is possible with the computer keyboard) and economic (i.e., saving a keystroke wherever possible). Some of the most commonly recognized patterns of language change are:

    (a) lexical compounds and blends: e.g., *weblish, shareware, netiquette, e-* and *cyber-* anything;

    (b) abbreviations and acronyms: e.g., *THX* 'thanks,' *IRL* 'in real life,' *F2F* 'face-to-face,' *some1* 'someone';

    (c) minimal to no use of capitalization, punctuation, and hyphenation: e.g., *cooperate* and, of course, *email* and *internet*;

    (d) generally less regard for accurate spelling and/or typing errors;

    (e) less or no use of traditional openings and closures: e.g., *Dear. . .* (sometimes *Hi* or *Hello* instead) or *Yours sincerely*.

Based on a sample of nine bulletin boards, Collot and Belmore (in Herring 1996) have compared a 200,000-word *Electronic Language Corpus* with traditional genres of written and spoken English. Noting the relative frequency and configuration of different linguistic features, they have found that the language is more 'involved' than 'informational,' less narrative (e.g., fewer makers of reported speech), and uses fewer overt expressions of persuasion. As such, the *netlingo* of this particular niche most closely resembles that of public interviews and letters (personal and professional).

Similarly, Baron (1998) has drawn a complex, linguistic profile of emails, concluding that they are a 'creolizing linguistic modality'—a hybrid of speech and writing in terms of format, grammar, and style. Again, the tendency is to break the traditional, rule-bound conventions of written language in favor of the more sociable-interactive orientation of speech.

5. Conversation/Discourse: Speech That Looks Like Writing?

The communicative/conversational style of internet language is best observed in the channels of synchronous CMC (or *netspeak*) with its imaginative attempts to overcome technological restraints (e.g., transmission time lags) and to reinstate social cues often absent from written text. Such channels are the open-ended, text-based exchanges of online chatrooms; the elaborate, text-based role-playing games of MUDs (Multi-User Domains); or, more recently, the graphical chat environments of Virtual Worlds.

Communication in these niches is highly interactive, with added demands for speed, spontaneity and, often, brevity; it is also more likely to involve multiple participants. As such, *netspeak* is invariably more dynamic, unpredictable, spontaneous, and public, and some of the most common strategies are those used in pursuit of brevity, paralinguistic restitution, relationship, and play:

    (a) letter homophones (e.g., *RU* 'are you,' *OIC* 'oh I see'), acronyms (e.g., *LOL* 'laugh out loud,' *WG* 'wicked grin'), and a mixture of both (e.g., *CYL8R* 'see you all later');

    (b) creative use of punctuation (e.g., multiple periods. . ., exclamation marks *!!!!*);

    (c) capitalization or other symbols for *EMPHASIS* and **stress**;

    (d) onomatopoeic and/or stylized spelling (e.g., *coooool, hahahaha, vewy intewestin* 'very interesting');

(e) keyboard-generated *emoticons* or *smilies* (e.g., **: – –**) 'smiling face,' **, –**) 'winking face,' **@ > – – ; – –** 'a rose');

(f) direct requests (e.g., *A/S/L* 'age, sex, location?' and GOS 'gay or straight?');

(g) interactional indicators (e.g., *BBL* 'be back later,' *IGGP* 'I gotta go pee,' *WDYT* 'what do you think?'); and

(h) with more elaborate programming, colored text, *emotes* (e.g., **{Sender} eyes you up and down**, **{Sender} cries on your shoulder**) and other graphic symbols (e.g., images of gifts and accessories in Virtual Worlds).

In reviewing the distinctive communicative style of online chat in two IRC channels, Werry (in Herring 1996) has characterized it as 'interactive written discourse.' In particular, he notes the complex organization of sequences and exchange structures, evidenced in, for example, the juxtaposition of conversational strands, short turns (usually only about six words), high degrees of 'addressivity' (i.e., the use of *nicks* (nicknames) to avoid ambiguity with multiple participants), and minimal backchannelling from listeners (e.g., *uh huh, mm hm*).

6. Stylistic Diffusion: The Spread of Netlingo

A popular claim made about *netlingo* is its proliferation beyond the immediate context of CMC. Coupled with the diffusion (and indeed codification into dictionaries and other official usage) of technical, computer-related terminology, and concepts (e.g., *multitasking, windows, hacking*), common examples of lexical diffusions from *netlingo* are *spamming* (i.e. sending electronic junk mail), *cyberspace, cyberculture, shareware, hypertext, snail mail*, and *flame* (a hostile interaction).

Also of interest is the impact of *netlingo* on other languages, as well as official and/or isolated moves towards reclamation and resistance such as reports of *CyberSpanglish* (e.g., *surfeando el Web* and *estoy emailando*) and the preference of *La Francophonie* for

terms like *bavardage* (rather than *chat*) and *un pirate informatique* (rather than *hacker*).

7. Metalanguage and Folklinguistics

Finally, as already indicated, the metalanguage of the internet is itself a potential site of sociolinguistic curiosity. In addition to labeling such as *weblish* or *netlingo*, other changes-within-changes are occurring all the time; for example, regarding the hyphenation and capitalization of netlinguistic terms (e.g., *E-mail > e-mail > email*, or *internet > Net > net*, or *Web > web*). There is also an intense public discourse about the perceived (negative) impact of *netlingo*, blamed for the 'death' of the apostrophe, the loss of capitalization, and the informality of communicative exchanges more generally.

8. Looking to the Future

As technologies of communication continue to develop and change, so too will associated linguistic forms and communicative practices. Some of the very latest technologies of communication which will inevitably impact on CMC are mobile phone text-messaging (SMS), Virtual Worlds (adding a visual dimension to chat), as well as voice-recognition and video technology. And so, where the demand for typographical speed and economy is heightened in one context of CMC, in others the ease and richness of face-to-face communication is being approximated ever more closely.

Verbal Duel

R. Ackerman

The term 'verbal duel' may refer to a contest, fight or to a friendly competition between two individuals carried out through language. Verbal duels adhere to strict implicit rules stipulating the ages, gender and social status of the contenders and their listeners as well as the range of topics suitable for dueling. The interpretation of the duel—either as an aggressive

game or as an act of real aggression—varies culturally, depending on the history of the relationship between the contenders, the setting in which the duel takes place and the code that is chosen. Some cultures treat verbal duels as aggressive games while others value them as real aggression. Even in cultures which treat them as aggressive games, the meaning of

the interaction may change according to the relative position of the participants and the history of their relationship. In every situation, the winner of a verbal duel normally leaves his opponent without retort.

1. A Basic Difficulty of Classification

The seriousness of a speech act (see *Speech Act Theory: An Overview*) in which two individuals exchange insults cannot be properly assessed without understanding the cultural background in which it takes place. The relationship between the individuals and the intentions behind their aggression will usually provide the audience with a clue as to its significance. The same utterance may be variously interpreted in different contexts. In some instances, the mutual verbal aggression is part of a long-standing relationship, and the phrases exchanged are quite conventional and formulaic. They are not meant to be taken seriously, least of all personally, and retaliation is frowned upon. They are rather an aggressive game or play, a 'joking relationship.' However, in another context within the same societies, the same utterance could carry a heavy semantic load if its message were to be taken seriously. The individuals insulting each other are also trying to destroy each other through words, lower each other's self-esteem as well as show superior verbal wit. In both kinds of duel—aggressive play and real aggression—strict adherence to sociolinguistic rules is crucial.

Among Quechua speakers, in agricultural activities, two teams compete against each other in physical and verbal feats. A man, or several, in one team insults a member of the other by hinting at his physical incapacity and sexual impotence. The topics chosen for these occasions are highly standardized. It would be unacceptable, for instance, to insult members of that man's family. The insulted party may win the duel by reversing the situation through his verbal prowess. This kind of verbal duel is highly public and no offense is socially permissible. In contrast, insults exchanged in private are referred to by the same term used for rape. They are far more personal, less standardized and more offensive. The winner of these private duels is the one who does not repeat himself or herself, and who can come up with the most creative metaphors.

2. Verbal Duels and Their Relationship to Social Norms

Often verbal duels select topics that are otherwise taboo in the culture and that stand in inverse relationship to what is considered proper social norms. They allude to inappropriate behavior. The topics vary a great deal since generally the aim of the duels is to lower and profane the opponent's self-esteem within the values provided by the culture. They may involve matters of personal and family

honor. Verbal abuse against members of the contenders' immediate family is common. A common pattern takes the form of direct accusations of improper sexual conduct, especially in relation to members of the addressee's family breaking sexual taboos. Additionally, the same result may be achieved through the use of sexual themes that are excluded from proper etiquette in reference to members of the addressee's family.

Research on North American Black youths describes that their insults make a great deal of allusion to the person of the mother, in all her physical, social, and sexual behavior. They are also implicitly subversive of White cultural values, by infringing upon as many taboo concepts as possible. Likewise, verbal duels among Turkish adolescents center, among others, on themes of passive homosexuality, bestiality, and improper behavior of female relatives. The attackers, on the other hand, all claim excess of masculinity and strength.

A researcher of Chamula (Maya Indian) verbal behavior provides an excellent example which illustrates the relationship between verbal abuse and social norms. 'The improper behavior implied in the duel is precisely the opposite of the behavior which accords rank and status to adult men in real life. The exchange begins with homosexual nuances and suggestions of incestuous or promiscuous sexual behavior on the part of the other's female siblings, continues with insults to the other's family, sexuality, and sexual apparatus, and concludes with a long exchange of directions between two sexual partners. Rapid sexual role reversal between the two players appears throughout' (see Gossen 1976: 138).

3. Duels and the Socialization Process: Rites of Passage

Verbal duels begin to take place during an intense period of socialization among children and adolescents who are learning and trying out the social world of adults. Even though verbal dueling is not limited to children and adolescents, it is often found among these age groups. Duels in these situations become the experimental ground on which the values of the adult world are dramatized. The insults of children and adolescents are often a mimicry of the more poignant adult ones. Among children, it is a matter of semantic oversimplification which reflects their incomplete acquisition of the sociolinguistic rules of their culture. Children transpose an insult which appeared to them to be effective in one setting into another. Adolescents are more adept at duels, though the sophistication of their duels is usually below that of their adult counterparts. Adolescent duels are usually stylistically and thematically simpler than those of adults, adhering more closely to formal rules.

While in some instances it is the case that adults have readier access to physical force, youths do not simply replace physical force by an alternative mode of violence. Rather, they choose an outlet in which the values of the adult world are dramatized. Youths are often excluded from the adult world or are not yet full participants in it. This is particularly true in terms of their exclusion from two areas of social life which are the focus of public attention: sex and prestige. And it is precisely these aspects of the adult world which become the acceptable focus of duels among adolescents. Duels then become the socialization arena in which the youths will get their training in the values that will be taken seriously later on in life.

4. Indirection

Verbal dueling is always done by means of indirectness. What is said does not literally express the meaning. The listener must engage in some form of nonliteral interpretation to understand the intended meaning. The message and the metamessage are not the same. Messages are carefully clothed in a veneer of verbal wit. To interpret them one must go beyond the literal meaning into the metaphorical one, as well as take into account relevant paralinguistic features. For these interpretations to be successful, one needs to be familiar with the particular dueling tradition.

The following account, given by a researcher of Black American English, illustrates indirectness in a verbal duel. 'A man coming from the bathroom forgot to zip his pants. An unescorted party of women kept watching him and laughing among themselves. The man's friends hip (inform) him to what's going on. He approaches one woman—"Hey, baby, did you see that big Cadillac with the full tires, ready to roll in action just for you?" She answers, "No, mother-fucker, but I saw a little gray Volkswagen with two flat tires"' (Kochman 1969: 27).

To the initiated, as well as to most people vaguely familiar with North American Black culture, it is clear that what the speakers are discussing has much more to do with sex, cross-sexual tensions, and insecurity than it has to do with automobiles. The metaphor used by the man emphasizes power and class. The woman retorts by building on the metaphor used by the man and reversing the implicit message. This building up of the response upon the original metaphor is called 'signifying' among the speakers of North American Black English vernacular. The woman here is clearly the winner. Her reply effectively reverses the claims of the original speaker without leaving the metaphorical realm chosen by the initiator of the exchange (see Mitchell-Kernan 1972: 174).

5. The Winner of a Verbal Duel

The aim of duels is often to destroy one's opponent with words. The winner must show superiority in a number of areas. Above all, winning at verbal duels requires the ability to manipulate language. The winner is the one who shows superior verbal skill in producing the most effective insults and who can respond to the challenge with an even more devastating statement. In addition, the winner must demonstrate his or her mastery of the duel rules. The permissible themes, codes and demeanor must be followed. Successful participants in a verbal duel adhere to the stylistic rules and demeanor. They avoid the two capital sins of verbal dueling: having recourse to everyday prose and having recourse to direct physical violence.

An example that brings together the qualities of a winner was provided by a researcher of Puerto Rican verbal duels. 'One cannot become embarrassed ... or become angry and curse, or even resort to the ultimate sanction of violence. In such a contest the self maintained in the interaction is attacked on two levels: its positive qualities are assailed; in addition, one is treated by the rest of the participants, not as a participant, a full social person, but as a mere focus of attention' (see Lauria 1964: 61).

6. Duels and Verbal Art

Insults employ unique stylistic techniques—rhyme, meter, or metaphoric language—while at the same time emphasizing creativity. These characteristics draw them closer to poetry, albeit an execrative one. A Black American verbal duel could begin with a persuasive speech event called 'rap' and then, after destroying an opponent, move on to the more indirect 'signifying.'

The following excerpt, aimed at rescuing someone already destroyed through words, reflects the free verse style of modern American poetry. Note in particular the author's use of parallelism at the syntactic level to emphasize the oxymora at the semantic level.

'Man, I can't win for losing.
If it wasn't for bad luck, I wouldn't have no luck at all.
I been having buzzard luck.
Can't kill nothing and won't nothing die.
I'm living on the welfare and things is stormy.
They borrowing their shit from the Salvation Army.
But things bound to get better 'cause they can't get no worse.
I'm just like the blind man, standing by a broken window.
I don't feel no pain ...'

Language Variation and Change: Dialects and Social Groups

Accent
J. M. Y. Simpson

A spoken variety of language is realized in speech-sounds: any one system of such sounds and their combinatorial possibilities constitutes an 'accent' of that variety of language. Just as a written language may be realized visually in different styles of print or handwriting (or in some cases in totally different writing systems), so a spoken language may be realized in more than one accent, even though it may be standardized to a greater or lesser extent in grammar and vocabulary. For example, Standard English is fairly homogeneous in grammar and vocabulary, but Standard English spoken by an American 'sounds' different from Standard English spoken by someone from Australia or Ireland.

Such differences of accent arouse interest from several points of view. The phonetician-phonologist studies the ways in which accents differ and how these differences can be described technically. The sociolinguist investigates correlations between accents and regional and/or social groups of speakers and also examines attitudes towards accent, that is, how a hearer makes judgments about speakers on the basis of their accents. Finally, in second-language teaching the problem arises as to *which* accent of the language being taught should be chosen as the model for learners. In this article these points are addressed by taking examples from Standard English, but the principles apply to any variety of language.

1. Differences between Accents

The point should be made first of all that, since accents of English vary phonetically and phonologically, it is impossible to describe the phonetics and phonology of English without specifying the accent(s) under discussion, for no one accent is 'the' accent of English.

If a phonemic framework is adopted for the description of an accent, one component of the description would be an inventory of the phonemes; another would be the allophonic realizations of these phonemes in various environments. Both of these may vary from accent to accent.

The number of phonemes available may differ. For example, most Scottish speakers of English will use different diphthongs in *tied* and *tide* while English speakers of English will pronounce these words as homophones. Thus at that point in the system the Scottish accent has one more phoneme than the English. On the other hand, most speakers of RP (Received Pronunciation, an accent of English, see below) will have six different vowel phonemes in the words *bad, balm, cot, caught, pull, pool*; most Scots will have identical vowels respectively in *bad* and *balm*, in *cot* and *caught*, and in *pull* and *pool*. At this point in the system, the Scottish accent has three vowels as against six in RP. Some American accents (for example, General American, see below) will have the same vowel in *balm* and *not*, so where English English has six vowel phonemes, some American accents have five (see Fig. 1). (Notice that what is under discussion in this article is not the language variety known as Scots but Standard *English* as pronounced by educated Lowland Scots.)

	General American	Scottish English	RP
bad	a	a	a
balm	ɑ		ɑ
cot		ɔ	ɒ
caught	ɔ		ɔ
pull	ʊ	u	ʊ
pool	u		u

Figure 1. Phonemes in General American English, Scottish English and RP.

Similarly allophonic realizations differ. For example, the same vocalic phoneme is used in a word such as *rope* by American, English, and Scottish speakers of Standard English; however, while a typical Scottish speaker will realize this as a rounded half-close back monophthong [o], the majority of speakers from England and the USA will realize it as a closing diphthong, the particular quality of which may range from [oʊ] to [ɜɣ].

A third difference concerns permissible sequences of phonemes in connected speech, the realm of phonological structure. For example, in General American an /r/ phoneme can appear postvocalically before a consonant and before a pause: thus *car* and *card* are phonemically /kar/ and /kard/; such an accent is termed 'rhotic.' Other rhotic accents of English are Canadian, Scottish, Irish, English West Country, some Indian, and some Welsh. But in RP an /r/ phoneme cannot appear in these positions, so that *car* and *card* are phonemically /ka/ and /kad/ respectively; such an accent is 'nonrhotic.' Other nonrhotic accents are Australian, English Midland, London, most New Zealand, most Northern English, South African, West African, and West Indian. Both rhotic and nonrhotic accents will, of course, permit an /r/ prevocalically, as in *red* /rɛd/.

A fourth area of difference concerns the characteristic selection of comparable phonemes to realize particular words. Thus *buoy, lever,* and *tomato* are respectively /'bui/, /'lɛvɾ/, and /tə'meɪtoʊ/ in General American but, with a different selection of vowel in the stressed syllable, /bɔɪ/, /'livə/, and /tə'matoʊ/ in RP.

Various phenomena observable in word-sequences may differ. Some 50 words in RP have different phonemes according to whether the words are stressed ('strong forms') or unstressed ('weak forms'). Thus *from* in *Where's he from?* is normally stressed and realized as /frɒm/; in *He's from London* it is normally unstressed and realized as /frəm/. Such an alternation is unknown in most Scottish accents. Similarly, a sandhi-form appears in some types of RP when a word ending in one of certain vowels is followed by a word beginning with a vowel, a 'linking-r' /r/ is inserted, thus *law and order* /'lɔr ən 'ɔdə/. This phenomenon is unknown in General American.

Finally, dynamic (or suprasegmental) features vary. Voice quality differs from accent to accent, such differences being described by the layman in impressionistic terms: to an RP-speaker a typical General American voice may sound 'strident,' while the typical RP-speaker's voice may sound 'effete' or 'languid' to an American. English worldwide has several regional sets of intonation tunes, differing in the number of tunes available and in their contours. The stress-patterns of individual words may differ: thus *magazine* is variously stressed on the first or last

syllable. Syllabification may vary: in Scottish English consonants can 'jump' across word boundaries to release syllables (e.g., *post office* /'pos'tɔfis/) but not normally in other accents. And rhythmic organization varies: *meter* will have syllable lengths (not vowel lengths) of 'long-short' in some American and Yorkshire, 'short-long' in Scottish English, and 'equal-equal' in RP (see Simpson 1979: 79–83).

Differences of this kind raise the important question of whether it is possible to posit one underlying phonology of the English language from which every accent can be derived. This seems impossible. The situation is rather that of a number of individual speakers who can understand each other, in spite of differences of accent. Indeed differences between speakers involve not only accent but vocabulary, grammar, idioms, and style. This consideration emphasises the fact that the idea of *a language* is merely a convenient fiction which facilitates the description of one aspect of human behavior (see *Language*).

2. Groupings of Speakers and Accents

In the particular case of English, the majority of accents are regional, belonging to geographical areas of various sizes. There exist, for example, identifiable Australian, Canadian, Indian, Irish, New Zealand, South African, and Scottish accents of English. Within such accents, it may be possible to make further distinctions. Thus the accents of the USA are grouped into three main types: Eastern (Maine, New Hampshire, and the eastern parts of Vermont, Massachusetts, and Connecticut); Southern (the Southern states); and General American (the rest of the Union). And within these it is in many cases possible to recognize finer differences of accent characterizing increasingly smaller areas. (Indeed the concept and the term 'General American' are rejected by some scholars precisely because of such differences within the accent in question.)

But differences of accent may correlate with factors other than regional: with social, religious, educational, or even political groupings, for instance, though it may not be possible to exemplify all of these factors from English. One unusual example is found within England (but not the other countries of the British Isles) in Received Pronunciation (RP). This grew up in the 'public' (i.e., exclusive boarding) schools of England, which, until the advent of broadcasting, remained virtually the only source of its propagation. It cannot, of course, be held to be the 'educated' accent of England: many highly educated Englishmen use other accents. Speakers of RP thus constitute a social, self-recognizing, accent-group. RP is therefore a nonregional accent within England itself, though outside England it is regional in the sense of marking a speaker as coming from that country. Again, it must be pointed out that RP is by

no means a homogeneous accent and that it is undergoing changes.

The investigator of how speaker-groupings correlate with accent is faced with problems of various kinds. Determining the accent itself may not be easy. For example, a speaker's pronunciation may not be consistent in successive utterances of the same words (see Labov 1966). This raises the issue whether it is possible to regard one of these competing pronunciations as 'the' pronunciation of the speaker and what conclusions can be drawn from such inconsistency. Moreover, how does one determine the relevant grouping? While it may be comparatively easy to assign membership of a religion or of a geographical area, in other cases the delimitation of the group itself is not obvious. For example, in determining social class, a variety of factors may be relevant—income, occupation, education, area of residence, leisure activities—and their relative importance also needs to be determined. Even when the principles of assigning groupings have been settled, the problems arise of deciding *how* typical of the group a given speaker may be and hence of generalizing from the accent of one speaker to that of a group. Such problems are not peculiar to the investigator of accent, of course: they confront the investigator of any sociolinguistic variable.

3. Attitudes to Accents

It follows from the definition of accent above that, contrary to popular usage, it is impossible to 'speak without an accent.' Every speaker has an accent. From a linguist's point of view, all accents are objects of interest and all are of equal value: an accent as such cannot itself be 'good,' or 'bad,' or 'educated,' or 'vulgar.' Equally it is impossible to set up some esthetic scale by which one may judge the euphony of an accent.

Nevertheless, judgments about accents *are* widely made. In everyday life, some accents are indeed regarded as socially preferable to others, or variously as beautiful, ugly, educated, vulgar, comic, bucolic, snobbish, and so on. Such judgments can be the result of sheer prejudice (for or against) or of transferring a judgment about a speaker to his speech; though irrational (or perhaps because of that), they can be very strongly held (see *Sociophonetics*).

Probably no generalizations are possible about which linguistic features will account for particular judgments (or prejudices). For example, within England a nonrhotic accent of English is socially preferable, but in the General American area it is a rhotic accent that is socially preferable. In British urban accents, the use of a glottal stop as a replacement (or realization) of intervocalic /t/ in such words as *water* is stigmatized but in RP a comparable realization of preconsonantal /t/ in a

phrase such as *that man* goes unremarked. It is therefore impossible to predict how a given accent will be judged except by taking into account particular hearers or groups of hearers. Support for this view is given by the finding that hearers who are asked to evaluate the accents of a language they do not understand are unable to make any judgments (Giles and Powesland 1975).

However, hearers who understand what is being said and who are part of the sociolinguistic fabric of the language variety in question will very quickly make judgments about accents, both in everyday life and in controlled sociolinguistic experiments. Where a number of accents are found which realize the same variety of language in a particular area, these may well be assigned a place on a cline of high-to-low prestige. Demonstrably on occasion, such judgments (or prejudices) are obviously about accents, and not about other characteristics of the speakers involved, since in the relevant experiments speakers are heard but not seen. Accents act as cues which arouse social expectations, and judgments about the speakers' personalities are made on the basis of these cues.

In such experiments, which employ the Matched Guise Technique, subjects hear tapes which include recordings of the same passage read by the same speaker but in different accents. The subjects are then asked to evaluate what they imagine to be different speakers in terms of such characteristics as intelligence, ambitiousness, friendliness, honesty, and so on. It is striking that the same individual can be ranked differently on such scales depending on the accent used. Indeed the actual content of a text, for example the quality of the speaker's argument, may be differently assessed according to the accent (see *Attitude Surveys: Question–Answer Process*).

All accents can fulfill the function of demonstrating the bonding or solidarity that holds within a group of some kind; an accent is a marker of group identity. There is evidence that speakers who belong to the core of the same social network will share an accent that is similar in the finest phonetic detail. One therefore assumes that these speakers want to conform to the accent of their peers. Other things being equal, one would further assume that a speaker would evaluate his or her own accent most highly. But other things are not always equal and in some cases a speaker will rank accents *other* than his own as being superior on some particular scale of values. Presumably in such cases there are two conflicting pressures, that of retaining one's accent in order to conform to the peer group and that of changing one's accent so that it resembles one perceived to be superior. Individuals will vary according to which pressure is felt to be more important, for the obverse of an accent's role as marker of group identity is its role as marker of an individual's identity, and this

includes group membership, both actual and desired. On occasion, speakers will temporarily change their accent in conversation with the intention either of emphasizing membership of the same group as their hearers or underlining their membership of a different group (see *Speech Accommodation*).

4. Model Accents for Language Learners

Second-language learners inevitably face the problem of learning the pronunciation of their new language. In the case of English (and many other languages) this should ideally involve choosing a model accent by taking account of certain factors outlined below. However, a genuine choice is not available to many learners for two reasons. It has to be admitted that after the 1940s the importance attached in the first decades of the twentieth century to pronunciation in language-learning and -teaching was largely forgotten, so that many native-English-speaking teachers lack not only awareness of the issues outlined in Sect. 1 but also the technical expertise to teach pronunciation adequately. In the second place, certain languages are vigorously promoted by governments and official agencies. Inevitably, the agencies of any one country will assume that an accent of that country should be the model for foreign learners; any ensuing difficulties or the possibility of alternative models are ignored.

It is, of course, crucial that the learner should acquire the essential articulatory skills. Given this, if the learner is living in an area where the new language is spoken, then he will presumably aim at the accent spoken by that group to which he would wish to belong, if of course he is aware of the relevant groupings and accents. But when the learner is in a country where the new language is not generally spoken and where there is a possibility of choosing from alternative accents, various considerations are relevant to deciding among them.

(a) From a phonetic-phonological point of view, the ideal model accent would be that which approximates in the greatest number of respects to the sound-system of the learner's own language. If such an accent does not exist, then the next-best model accent would be that which is simplest in terms of phonemic inventory, phonological structure, and dynamic features.

(b) If the learner is going to encounter only speakers with a particular accent, for example, by going to live in an area where it is spoken, then it is only reasonable to learn that accent. Otherwise, if the learner is going to meet speakers with a variety of accents, it is advisable to avoid adopting an accent intelligible in only a restricted area.

(c) If possible, an accent should be selected which is expounded in a sufficient range of teaching materials.

(d) Consideration should be given to the accent of any available native-speaking teachers.

(e) A model accent should not be perceived negatively, because of either social or political reasons, among the users of the language (whether native speakers or not) with whom the learner will come in contact.

Unfortunately, these considerations may conflict. For example, RP was brilliantly investigated by Daniel Jones and was expounded by him as a model for foreign learners. Although Jones maintained that learners should be free to choose whichever accent they find appropriate, RP is virtually the only accent employed in the plethora of English as a Foreign Language (EFL) teaching-materials emanating from the British Isles. However, the number of speakers of genuine RP is extremely small. This means that the number of RP-speaking teachers is low and also that the learner's chances of meeting RP-speakers in the British Isles is low. Moreover, the phonology of RP is complex: it has a larger vowel system, with many diphthongs, than most accents of English and displays the intricacies of such things as weak versus strong forms and linking-*r*. More importantly, though RP has prestige in some places, principally England, it is negatively perceived in others and may even arouse hostility, being associated (whether rightly or wrongly) with colonialism and similar pretensions. Nevertheless, RP is still regarded, rather curiously, as 'the' accent of English by certain European educational authorities (see Abercrombie 1990a).

Another possible model is General American, the accent used in EFL materials produced in the USA and other countries coming under the influence of the USA. It is from a practical point of view preferable to RP: it has a simpler vowel system and is rhotic, so that an ⟨r⟩ which appears in spelling is pronounced. Apart from that, it is readily understood in a very large part of the English-speaking world. But it too is disliked in certain quarters (for example, by some from Portuguese- and Spanish-speaking American countries who may nevertheless have adopted it as a model) as having colonialist overtones, while by certain Europeans it is unreasonably regarded as being in some vague way undesirable.

It has been suggested that a Scottish accent of English would be an excellent model on the undeniable grounds that it has a simple vowel system (the qualities of which conform very closely to what could be called 'Standard Average European' vowels), it is rhotic, and it is highly intelligible internationally. Furthermore, it is widely admired and free from the political associations of RP and General American (see Abercrombie 1975, 1990a). However, there is a total lack of teaching materials using this accent as a model and the number of teachers who speak with

this accent is strictly limited. There is in any case no tradition of a Scottish accent being used as a model.

The question can properly be asked whether it is necessary that a model accent should be a *native* accent of English at all. Admittedly it is the case that some foreign accents of English can be negatively perceived, either because they are difficult to understand or because they inadvertently signal inappropriate apparent attitudes, such as arrogance, through the use of dynamic features, for example, voice quality or intonation, that are neutral or even convey friendliness in the learner's language, but send very powerful negative messages in English. Nevertheless other nonnative accents that are immediately intelligible, are devoid of unfortunate overtones, whether political or attitudinal, and can be regarded as being on a par with native accents. For example, the accent used by many fluent English-speakers whose native language is Arabic is for these reasons perfectly acceptable (indeed in many respects, though not in voice quality, it is very like a Scottish accent) and there would seem to be no reason for suggesting that such speakers should adopt a native accent. Indeed it has even been suggested (see Abercrombie 1990a) that French should be the basis for the accent of French learners of English.

On the other hand, certain accents of even native speakers from the 'Outer Circle' of the New Englishes (countries in the Caribbean, the Indian sub-continent, and West Africa) are at present internationally not widely intelligible (perhaps because of their syllable-timing) and thus would not be the best accents to take as models (see *New Englishes*). This situation will change, of course, if these accents become widely known outside their home areas. It should be emphasized that no accent is objectively more comprehensible than any other; familiarity with an accent is the key to its comprehensibility.

Finally, it may be observed that because an accent is so strong a marker of individual personality, speakers may be totally averse to adopting one different from that which they habitually employ. This reluctance may characterize certain learners of English, who do not wish to be seen to belong to any English-speaking group at all, and also some native speakers of English who have moved from their original home: the latter may sometimes argue explicitly that their accent is a native, hence 'correct,' one and in no way inferior to any other. Both groups may underestimate the apparently negative attitudes they convey or even the very real problems of intelligibility they present to their hearers.

Adolescent Peer Group Language
R. L. Taylor

Much of the reality and significance of adolescent social life is concealed from adult society by linguistic devices contrived by youths for this purpose. However, the distinctive terminology or language of adolescents is more than an instrument of concealment or obfuscation, for it reflects their perceptions and assessments of their status in society, their values, interests, beliefs and world view, and serves as an index of solidarity and alienation. As a group phenomenon, adolescent language crystallizes, objectifies, and communicates the collective experiences of youth as these experiences are shaped by such factors as age, gender, class, race, and other differences among adolescent subgroups in a society. This article focuses first on the social conditions that give rise to the language of adolescents and its role in promoting group definition and distinctiveness; particular attention is then given to the lexis of Black adolescents as an illustration of some of the important differences in the sociolinguistic patterns of adolescent subgroups.

1. Families and Peers in Adolescence

Adolescence, the period of transition from childhood to adult status, is widely recognized as a crucial stage in human development. It is characterized by changes

at all levels of integration: social, psychological, and physiological. As a social phenomenon, adolescence in modern, industrial societies is marked by the experience of status discontinuity in which adolescents find themselves in an ill-defined marginal position: they have lost their former childhood status but have not yet acquired the status of the adult, and they are confronted with few norms and clearly defined role expectations to guide their behavior. As a psychological phenomenon, adolescence is a period in which the adolescent is expected to replace an ascriptive identity, based on place in family, by a more mature and socially recognized identity based on universalistic criteria (Eisenstadt 1956). Insofar as adolescents are segregated during this period, they are forced to look to each other to develop their own standards and codes of behavior as a means of acquiring a temporary identity in the flux of adolescence.

The emergence of adolescent society and culture, embodied in distinctive norms, values, and a language intelligible to members of this age-grade, can be traced to the problems of socialization associated with advanced industrialized societies, where a highly specialized division of labor, requiring a prolonged period of education and training in preparation for the assumption of adult roles and responsibilities, prevails (Schwartz and Merten 1967). Such extensive preparation forestalls the age at which self-support and independence begins, and when an identity based on mature roles can be consolidated. Hence, adolescent subcultures attempt to solve problems arising from the interim position of adolescents, providing a sense of security and belonging during a period of status discontinuity.

Through age segregation, secondary schools provide the major locus of contact among the various segments of local adolescent populations, and are the typical settings within which adolescent societies emerge (Coleman 1961). In the adolescent subculture of the school, peer group interactions are guided by distinctive evaluative standards and status terminology which form the basis of the peer group's prestige hierarchy, and determine the kinds and amount of respect the occupant of a status category can claim in the adolescent social system. While the status system that evolves in schools is influenced to some degree by criteria borrowed from adult society, the multiplicity of discrete norms which regulate relations between peers are integrated into a relatively coherent system by distinctively adolescent conceptions of personal worth. Such peer group norms enforce a degree of conformity upon its members that is considerably tighter than that found among adults, and they pattern their preferences, sentiment, and behavior in matters of appearance, dress, speech, and other expressive activities in ways that are highly predictable. Motivation to comply with such norms is

inspired as much by the adolescent's need for acceptance and fear of rejection, as by the desire to alleviate the frustration and confusion associated with an interim status.

Various media of mass communication (i.e., radio, newspapers, television, etc.) play a major role in linking youth together from different localities, in nationalizing their interests and concerns, and in strengthening their values and norms. Yet many aspects of adolescent culture remain hidden behind a veil of secrecy erected to escape the scrutiny and control of adults. The language of adolescents becomes an effective means of concealing their interests, sentiments and experiences from adults, while sharing them with members of their peer group. To be sure, not all adolescents in a society speak the same language nor share in the same subculture. There are in fact important differences in the sociolinguistic patterns of adolescent subgroups which derive from a diversity of experiences associated with class, ethnicity, race, and gender. Therefore, adolescents may be expected to exhibit different subcultural patterns of behavior depending upon whether they are characterized by one or more of such variables.

2. The Language of Adolescents

The growth in influence of peer groups on the evolving perceptions, attitudes, and linguistic behaviors of youth during adolescence continues a process begun much earlier in the life cycle. Opie and Opie (1959) describe how children's games and activities bring them together in age-graded groupings where large amounts of lore and language are shared and contribute to the creation of a separate childhood culture. However, the language of adolescents is distinguished from the language of children by its intended purposes, functions, and consequences for behavior and experience (Gusdorf 1965). For children, language is the medium through which the world is discovered and the means by which society and people are increasingly understood. Its functions are integrative and inclusive. The linguistic forms of adolescents have their function as markers of social identities and group exclusiveness, and are sometimes used as weapons to oppose, confuse, or offend (Romaine 1984, Rose and Ross 1994).

2.1 The Functions of Adolescent Language

Few features of the lives of adolescents during this transitional period so clearly reveal their movement away from the family and their integration into a peer-defined social world as the special language they adopt for use in communicating with each other. The acquisition of such a language makes the adolescent a member of two linguistic communities, one essential for communicating with adults at home and in

school, the other necessary for conversing with peers (Lewis 1963). The reason why such a special language evolves and is so tenaciously maintained must be sought in its functions. At least three major functions can be discerned.

Basic to the emergence of adolescent language is the drive for autonomy or independence from parental authority and the need for bonding with members of one's peer group. The use of slang, taboo words and alliteration, the style of articulation, and other kinds of verbal play, proclaim for the adolescent membership in, and allegiance to, a particular group, and serve as forms of resistance to adult control. Hence, the special language of adolescents arises from the need for differentiation and social distance from adult society, and functions as an instrument of in-group solidarity and distinctiveness. In order to maintain its function as a marker of group distinctiveness and solidarity, and to minimize the potential encroachments of adults, adolescent terminology constantly changes: old terms replaced by new ones to refer to roughly the same phenomena, thereby preserving the secret codes by which in-group members identify and communicate with one another (see *Slang: Sociology*).

In addition to its role in promoting group identity and cohesiveness, the language of adolescents is a means of expressing the values and experiences of group members. The use of a special language, whether employed by adults (e.g., medical students, academics, gamblers, etc.) or by adolescents, has much the same function for both groups, namely, to facilitate communication among individuals who share common interests and concerns, and who need a common vocabulary for talking about such matters.

A good part of the interests and concerns of adolescents revolve around such forbidden topics as sexual activities, drinking, drugs, and lawbreaking, for which a special vocabulary unintelligible to adults is required. Slang and elliptical utterances, vague in reference, are shorthand devices to save time and effort by summing up complex and recurrent phenomena and experiences. Although intended for a different purpose, Bernstein's (1973) distinction between 'elaborated' and 'restricted' language codes which are associated with different systems of social relationships, could well be used to illustrate the differences between adolescents and adults in the way they use language (see *Bernstein, Basil; Code, Sociolinguistic*). By 'elaborated code' Bernstein refers to a relatively abstract speech style which orients the user to universalistic meanings, where principles and operations are made linguistically explicit. It allows for subtle differences in meaning by utilizing qualifications, and does not assume a high degree of shared contextual experience between speaker and listener. Such codes employ a widely varied vocabulary and complex syntax, as evidenced by a high proportion of subordinate clauses, conjunctions, uncommon adverbs, passive verbs, and adjectives. In contrast, the restricted code is a concrete and egocentric speech style which assumes a high degree of shared contextual experience between speaker and listener, is oriented to particularistic meanings, and is emotionally expressive. Restricted codes are characterized by fairly simple syntax, make use of a high proportion of pronouns, especially 'you' and 'they,' and tag phrases (e.g., 'stuff like that'). The tendency of adolescents to employ a restricted language code is related both to the 'egocentric' form of consciousness typical of this age group (i.e., the failure to distinguish between what they and others think about), and the desire to communicate with peers in a style of discourse that reflects their common experiences and assumptions (Britton 1970).

The restricted speech code employed by adolescents might more appropriately be referred to as their 'pubilect' or dialect of puberty, following terminological practices in linguistics. As Danesi (1989) has shown, three basic psychosocial categories of speech programming characterize pubilect in its various manifestations: emotive, connotative, and socially coded language programming. The tendency of adolescents to externalize strongly felt emotional impulses, accompanied by such bodily reactions as rapid increases in rate of speech, expressive voice modulations, simplified clause structure, and the like, are all manifestations of emotive language programming. As the most dominant aspect of the adolescent's structuring of speech acts, emotive language programming inspires an overabundance of exclamations, interjections, and grunts in their discourse which serve to call attention to their feelings, attitudes, and opinions. Connotative language programming refers to the tendency to invent new terms and idioms, or modify the meaning of existing ones, in ways that evoke vivid images or sum up complex phenomena in one or several words. While adolescents may experience some difficulty in giving precise definitions of such terms as *awesome, cool, nerd, geek*, or other terms which may be in current use among peers, the connotations of such terms are clearly understood and prompt them toward expected emotions and actions. Socially coded language programming refers largely to the manner in which adolescent discourse is structured to promote intragroup bonding. Much like adolescent norms regarding correct appearance (i.e., clothing, grooming, makeup, etc.), socially coded language programming reflects adherence to peer group norms regarding style of verbal discourse, and highlights the fact that youths are highly conscious of how they 'come across' linguistically in the company of their peers.

Establishing status and associational patterns within the adolescent social system are other important functions of the special language of youths (Labov 1982). Adolescent society provides a status system and terminology which enable youths to engage in predictable and consistent interactions with their peers, and to acquire a sense of personal worth based on subcultural standards rather than the norms of adult society. The status terminology employed is affectively coded such that a youth's status in the local prestige hierarchy is partly a function of the meanings associated with the terms peers use to connote his or her character and group affiliations (Schwartz and Merten 1967). These terms have laudatory or pejorative connotations and are in part related to the adolescent's interpersonal skills and accomplishments, as measured by the norms, standards, and values of the peer group.

In the school-based social structure of adolescents, social differentiation typically takes place along two dimensions: one relating to lifestyles (i.e., modes of dress, speech, demeanor) which give rise to horizontal social strata; the other relating to highly esteemed interpersonal accomplishments and talents which constitute the vertical dimension, according to which the adolescent's rank and popularity within one of the horizontal social strata is established. While the status terms used to assign peers to one or another status category within the system are likely to reflect to some degree the socioeconomic characteristics of the local community, adherence to differentially evaluated adolescent life styles and associated values are more precise determinants of assignment to prestige categories (Eckert 1988). Various terms are used to refer to high and low status category affiliations within the social structure of the school. At different times and in different places, these categories may have different names and styles. Such terms as *collegiates, socies* (for socialites), *jocks,* and *Preppies,* have sometimes been used as status terms for adolescents affiliated with elite groups within the school system, while terms like *greasers, hoods, scraggs,* and *freaks,* have been applied to those of low standing. Such terms define the polar extremes between which the majority of adolescents, sometimes referred to as *normals, out-of-its,* or *in-betweens,* form a heterogeneous category.

3. Gender-specific Uses of Adolescent Language

Beyond the general functions of adolescent language noted above are gender-specific uses of peer group language. Differential patterns of socialization and extensive interaction in single-sex peer groups account for some of the gender-specific uses of language found among adolescents, and for differences in social structure between peer groups (Romaine 1984). It is a common observation that boys and girls learn different ways of speaking and different rules for interacting with their peers (Meditch 1975), and that such differences appear at a fairly early age (Haas 1979). Observed differences in speech and behavior patterns involve much more than the simple imitation or assimilation of adult 'genderlects' and rules by school-age children, but are learned from peers at a time when boys and girls interact socially primarily with members of their own sex (Brooks-Gunn and Matthews 1979; see *Gender and Language*). Groups of girls and groups of boys engage in different types of activities (e.g., skip rope vs. football) which entail different patterns of interaction and involvement. Such differences in social organization and associated patterns of interaction contribute to gender-specific patterns of language use among adolescents (Maltz and Borker 1982).

Since boys and girls typically interact in homogeneous groups and in different social contexts, they tend to develop different genres of speech and different skills for doing things with words. The peer-group networks of adolescent females are typically smaller, and games or other recreational activities are generally cooperative and noncompetitive. Differentiation between girls is a function of closeness rather than power, and groups tend to be nonhierarchical. Friendship involves intimacy, mutual commitment, and loyalty. The idea of 'best friend' is central for girls. When disputes or conflicts arise, the group breaks up. Because of the inherent contradiction in the structure of girls' social relationships created by adherence to an ideology of equality and cooperation in interactions on the one hand, and the reality of difference and conflict on the other, girls learn to deal with the conflicting pressures through the use of language in several ways: (a) to create and maintain relationships of closeness and equality; (b) to criticize others in acceptable ways; and (c) to interpret accurately the speech of other girls (Maltz and Borker 1982). Through talk, girls learn to give support, to use inclusive language such as *let's, we could, we're gonna,* in enlisting the cooperation of others, and to direct others in task-oriented activities without appearing bossy. Since closeness is manifested by sharing secrets and other information that could be used against one another, girls learn to read the intent and loyalty of others, given shifting relationships and indirect expressions of conflict (Goodwin 1980).

By contrast, boys' groups are typically larger and more hierarchically structured than girls' groups. Relative status in the hierarchy is paramount and is the one thing that boys learn to manipulate in their interactions with one another. Though members of a group may often deny the existence of a leader and insist upon an ethic of equality, certain linguistic practices and patterns of behavior clearly reveal the

hierarchical and power-oriented nature of such groups (Labov 1982). Posturing and counterposturing is a prominent feature of the male adolescent social world, where patterns of speech are designed to accomplish at least three objectives: (a) to assert one's position of dominance; (b) to attract and maintain an audience; and (c) to assert oneself when other speakers have the floor (Maltz and Borker 1982).

Perhaps the best-documented sociolinguistic aspect of boys' peer groups is the use of speech for the expression of dominance (Savin-Williams 1976). As Maltz and Borker (1982) have shown, social success among boys is based on knowing how and when to use words to express power. Verbal dueling, storytelling, joke-telling, and other narrative performance events are highly valued and cultivated in boys' peer groups (see *Narrative, Natural*; *Verbal Duel*; *Speech Play*). An important sociolinguistic skill a boy is expected to learn is how to get the floor to perform, maintain his audience in the midst of a series of challenges, and successfully complete his performance. Boys learn to assert their identity and opinions in such contexts by side comments, putdowns, and challenges. Although some of the most extensive research on the verbal skills of male adolescents has been conducted in Black communities in the USA (Kochman 1972, Labov 1972), research conducted in other countries (e.g., Turkey) and on other populations (e.g., rural youths) reveals similarities in the speech patterns and functions of language across adolescent peer groups.

These patterns of adolescent speech and strategies for management of social interaction show marked continuities with adult sex-specific patterns of speech and behavior. Storytelling, arguing, and verbal posturing are common features of the speech style of men and boys. Verbal aggression, in the form of practical jokes, put-downs, and insults are considered normal among friends (LeMasters 1975). Women, on the other hand, employ a mode of speech that is more interactional, with more frequent use of personal and inclusive pronouns such as 'you' and 'we.' They send out and look for signs of agreement and engagement, and seek to create continuity in conversation. While elements of conflict, competition, and criticism occur in the conversations of women, such elements are more often disguised or conveyed in an idiom of support that give them a distinctive tone (Kalčik 1975). These and other observed differences between male and female conversational styles suggest that patterns of interaction and socialization in sex-specific peer groups lead to particular styles of discourse which prevail in adulthood. To a considerable degree, adult patterns of friendly interaction involve learning to overcome some of the gender-specific styles of discourse typical of adolescents (Maltz and Borker 1982).

4. The Language of Black Youth

As noted above, a considerable body of sociolinguistic work exists on the idiomatic usage and verbal skills of Black (African American) adolescents in the USA. Speech features of Black teenage idiom, once thought to be deficient or unintelligible, were discovered to have the properties of a conceptual and rule-governed system which, though related to mainstream usage, incorporates aspects of experience that are culturally specific (Smitherman 1977, Labov 1972). A number of terms have been used to refer to the language of Black youth: 'Afro–American slang,' 'Black English,' 'soul-talk,' 'jive-talk,' 'Black argot,' African–American street speech, and the like. In her fine-grained sociolinguistic analysis of Black teen language, Folb (1980) uses the phrase 'Black English vernacular vocabulary' to refer to the mixture of general slang, argot, Africanisms and culture-bound idioms that make up the pool of Black vernacular expressions. Black youth invent and utilize a terminology which serves the referential functions of providing labels for concepts and experiences that are particular to their subculture and that provide an emotional and critical outlet for group feelings (Goodwin 1990, Mitchell-Kernan 1980).

Other social functions are also apparent in shaping the vernacular expressions of Black youths (and adult usage as well). Among subgroups of Black teenagers and adults, Black vernacular serves not only as an instrument of group definition and solidarity but as a marker of the separateness of Black Americans as a distinct ethnic group. Such vernacular expressions as *blood, bleed, soul brother, soul sister*, among others, are terms used to refer to a kind of kinship that unites Black people on the level of group identity, while maintaining social distance between the Black community and other speech communities (see *Ebonics and African American Vernacular English*).

For many Black adolescents, introduction to the vernacular lexicon comes early in life—even before some have reached the stage of real comprehension. They mimic older siblings, parents, relatives, and friends of the family. Along with the vernacular, children learn the paralanguage and body language appropriate to its use (see *Kinesics*). The period during which youngsters become the most ardent users of vernacular vocabulary is between 10 and 13, while the period between 16 and 19 is a time for expanding and consolidating knowledge of the vocabulary (Lerman 1967). Although gender does affect access to vernacular vocabulary, as well as the scope, depth, sureness of knowledge, and usage, vernacular vocabulary usage is not exclusively a male phenomenon (Mitchell-Kernan 1972). Vernacular vocabularies relating to such common activities as partying, dancing, male–female interactions, sexual

301

preferences and habits, and drug-related activities are widely shared among males and females, as are certain expressive and manipulative aspects of verbal behavior such as *signifying, sounding,* or *playing the dozen,* all of which refer to well-organized speech events which occur with great frequency in the verbal interactions of Black adolescents (see *Verbal Duel; Speech Play*). Nonetheless, females use less vernacular vocabulary in their conversations than do males, in part because the latter are involved in a wider range of activities that generate such vernacular expressions, and in part because of the greater family and community constraints to which females are subjected. Though much of the vernacular vocabulary of Black youths is known and shared across socioeconomic and geographic boundaries, there are, nonetheless, disparities between middle-class adolescents and their inner-city counterparts based on differences in degree and kind of exposure to certain environment-bound life experiences, and the type of terminology that gets generated and used (Folb 1980).

As the preceding implies, Black vernacular vocabulary is learned in context, i.e., in the context of shared experiences that come from common life conditions which provide a frame of reference enabling Black youths to decipher the meanings for a variety of vernacular terms that many have heard since childhood. Hence, the meanings of many vernacular terms are difficult to grasp or interpret outside of this shared perspective, and apart from the paralinguistic and kinetic elements which accompany their use. Indeed, the kinetic element, both as it relates to body movements, gestures, and facial expressions, and a preference for terms or phrases that possess the quality of rapid and unrestricted movement (e.g., *dig, stepping, groovy, hustling*), is a prominent feature of Black vernacular expressive forms, and distinguishes the speech events of Black adolescents from those of their White counterparts (Kochman 1972, Labov 1972).

Chain Shifts

G. J. Docherty and D. J. L. Watt

1. Chain Shift: Definition

Chain shift refers to a type of sound change whereby changes in a vowel's phonetic quality trigger changes in one or more of the other vowels in the system, without affecting the number of phonetic contrasts the system expresses. The simplest subtype is the minimal chain shift (Labov 1994: 118–9). A vowel /B/ changes over time in quality, vacating the region of vowel space it previously occupied; a vowel /A/ then comes to occupy that part of the space. Contrast between /A/ and /B/ is thus preserved, although the actual phonetic nature of the contrast will have altered. This process can be represented thus:

$$/A/ \rightarrow /B/ \rightarrow$$

The second basic subtype is the extended chain shift (Labov 1994: 119). This involves coordination of minimal chain shifts, such that as /A/ moves to occupy /B/'s vacated space, /B/ moves into the space left by a third vowel /C/, and so on.

$$/A/ \rightarrow /B/ \rightarrow /C/ \rightarrow /D/ \rightarrow \ldots$$

Chain shifts, then, perpetuate the system of oppositions expressed by the vowel system, and should therefore be distinguished from merger. Merger occurs when /A/ moves into the space occupied by /B/, but /B/ does not move away to compensate for /A/'s encroachment. Two formerly contrastive elements collapse together, becoming homophonous, and thereby reducing the number of contrasts by one. Since such a loss is argued to reduce the system's capacity to express lexical distinctions, chain shift acts as a means by which vowel systems can optimize communicative potential by regulating their internal structures.

2. Labov's Principles of Chain Shift

In modern (historical) sociolinguistics chain shifts are most closely associated with the work of William Labov (see *Labov, William; Sociolinguistic Variation*). One of the fundamental contributions of the Labovian paradigm to the field has been the elaboration of the principles appearing to underpin chain shift, as evidenced by historical and synchronic observations. Labov's principles build on the work of earlier analysts such as Sweet (1988), Haudricourt and Juilland (1949) and Martinet (1955), but are also generalized to take account of synchronic developments in the vowel systems of a range of languages. Stated in a basic form that applies to completed chain shifts (rather than ongoing synchronic ones), the three principles are:

> PRINCIPLE I: In chain shifts, long vowels rise.
> PRINCIPLE II: In chain shifts, short vowels fall.
> PRINCIPLE IIA: In chain shifts, the nuclei of upgliding diphthongs fall.
> PRINCIPLE III: In chain shifts, back vowels move to the front.
> (Labov 1994: 116)

3. The Great Vowel Shift

One such reconstructed historical chain shift—and indubitably the best-known, most thoroughly researched of all chain shifts—is the series of changes affecting fifteenth-century southern Middle English (ME) known as the Great (English) Vowel Shift (GVS). First analyzed as a unitary phenomenon by Luick (1896) and later Jespersen (1909), it exemplifies best Principle I, in that the ME long vowels /aː/, /ɛː/, /eː/, /ɔː/ and /oː/ all raised by one height. The close vowels /iː/ and /uː/, unable to raise any further, 'sidestepped' the rising /eː/ and /oː/ by diphthongizing, their nuclei dropping one height to [ei] and [ou], respectively. Subsequently, these fell further (Principle IIA), giving the modern /aɪ/ and /aʊ/ diphthongs. This sequence (with later developments in parentheses) can be summarized as follows:

ME		ModE			Example
iː	→	ei	→	(aɪ)	*five*
eː	→	iː	→	iː	*geese*
ɛː	→	eː	→	iː	*clean*
aː	→	ɛː	→	(eɪ)	*name*
uː	→	ou	→	(aʊ)	*house*
oː	→	uː	→	(uː)	*goose*
ɔː	→	oː	→	(əʊ)	*goat*

The GVS is generally agreed to have been completed by the late sixteenth or early seventeenth centuries, the final stage being the raising to /iː/ of the merged

ME /ɛː/ (e.g., *meat*) and /eː/ (e.g., *meet*). (Note that there are a small number of exceptions, such as *steak, break, great, broad,* etc.)

Debate continues over how the shift started (Lass 1999, Stockwell and Minkova 1999). Of the two main camps, the first follows Jespersen (1909) in believing that the GVS was triggered by diphthongization of /iː/ and /uː/, a change which stimulated /eː/ and /oː/ to rise into the resulting gaps. This position exemplifies the pull or drag chain model, whereby vowels vacating their former positions 'pull' others along behind them. The second camp adheres to Luick's (1896) account which reverses this order of events: as they raised, /eː/ and /oː/ shunted /iː/ and /uː/ aside (the push chain model). Luick's account incorporates aspects of a drag chain, since as /eː/ and /oː/ ousted /iː/ and /uː/, so /ɛː/ and /ɔː/ rose behind them. An element common to both approaches is the notion of systemic symmetry: what applies to back vowels will apply to front vowels at equivalent heights, and vice versa.

4. Ongoing Chain Shifts

The framework within which historical phonologists developed the chain shift model persists in modern sociolinguistics, with Labov's work, in particular, seeking to unite generalizations emerging from post hoc reconstructions of historical sound changes with research motivated by the axiom that synchronic sound change (see *Sound Change*) can be observed as it happens. Findings emerging from large-scale instrumental studies of vowel variation in North American English (Labov et al. 1972, in press, Labov 1991, 1994) underlie a broad typology postulating two major patterns of chain shift. The first—exemplified by the so-called Northern Cities Shift (NCS)—is characterized by a 'clockwise' rotation of the short vowels /i/, /e/, /ʌ/, and /o/ plus the long vowel /oh/, that is triggered by the raising of /æ/ to the position occupied by /iə/ (we conform above to Labov's phonemic notation system, which differs somewhat from IPA notation). The NCS exhibits elements of both push and drag chains, and is schematized in Fig. 1; the numbers represent each step of the sequence.

The NCS affects the English of the industrial inland northern USA but is most advanced in the region's largest cities (Syracuse, Rochester, Buffalo, Cleveland, Toledo, Detroit, Flint, Gary, Chicago, Rockford) (see *The Atlas of North American English: Methods and Findings*). NCS-type changes are also reported to be underway in other US varieties and parts of Canada.

All three of Labov's principles are argued to govern the NCS, though an additional factor—peripherality—is invoked to explain why in chain shifts falling vowels do not clash with vowels rising towards them. Peripherality is not an absolute measure but is defined relative to the vowel system as a whole, and is modeled in terms of two parallel 'tracks.' The peripheral track runs around the perimeter of the vowel space, while the nonperipheral track sits within the peripheral track. Vowels raise and front along the peripheral track, but switch to the nonperipheral track when falling or retracting (Labov 1994: 177).

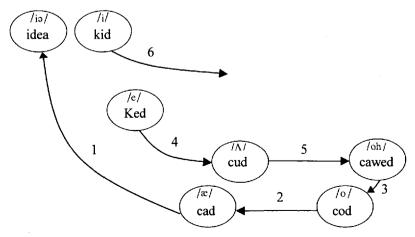
Principles II and III are less well exemplified in the historical record, with Principle II appearing to be of greater relevance to synchronic variation (see below). Principle III, however, is invoked to account for substantial historical evidence of back-vowel fronting in a wide variety of languages at many periods. With respect to the GVS, Principle III could have governed the fronting of ME /oː/ to


Figure 1. The Northern Cities Shift (after Labov 1998. Reproduced with permission).

[ø:] in northern British English dialects, a development, which—owing to the consequent lack of pressure on /u:/ from below—did not necessitate diphthongization of ME /u:/ in these varieties (preserving forms like [hu:s] 'house' and [du:n] 'down' which persist in Northumberland and Scotland. [o:], presumably in accordance with Principle I, then raised to [y:] and later unrounded to [i:], as in *boot, moon, do*, etc.; see Lass 1999).

The addition of the peripherality factor allows Labov to collapse the three principles to a single statement ('In chain shifts, peripheral vowels become less open and nonperipheral vowels become more open'). He claims this applies to the fronting of back vowels as well as raising/lowering in the height dimension, and it is clearly relevant in the description of the second major chain shift underway in contemporary American English. The 'Southern Shift,' affecting the dialects of the southern, south Middle Atlantic and south-midland states, involves laxing and centralization of long close and midvowels (Labov 1991, 1994, Labov et al. in press). Contrary to the NCS, its rotation is 'counterclockwise,' though the sequence appears to be less consistent than is the case for the NCS. Labov generalizes the Southern Shift to govern the vowel systems of dialects in southern England, Australia, New Zealand, and South Africa. Its operation in these varieties consequently becomes difficult to explain in terms of contact and resultant diffusion of innovations between northern and southern hemisphere Englishes. We must therefore consider system-internal explanations of the raising of nonclose vowels and the fronting of back vowels (see especially Trudgill et al. 2000). These processes are argued by some scholars to result from properties of vowel systems which arise from the mismatch between the communicative needs of speakers/listeners and the limitations imposed on them by vocal tract morphology and the auditory system. Some of the arguments proposed in support of this position are discussed in the following section.

The first two of the three main approaches to the explanation of why chain shifts are triggered in the first place are based on aspects of speech production and perception that are claimed to be universal (it ought, therefore, to be possible for chain shifts to occur in any spoken language, at any time). The first emphasizes the trade-off between articulatory constraints and discriminability of vowel sounds, and the perpetual instability of vowel systems resulting from the tension between the two. Vowels raise and front, it is hypothesized, because the lower back area of the vowel space is overcrowded: although vowel systems tend toward phonological symmetry, the articulatory space available for vowel production is inherently asymmetrical (Haudricourt and Juilland 1949, Martinet 1955, Samuels 1972). Such overcrowding

will obviously be more acute in languages featuring three or four distinctive vowel heights (such as Germanic and Romance languages; note that most of the languages for which Labov reports completed or ongoing chain shifts are members of these groups). Lindblom (1986) argues cogently for this position, stating that (a) the articulators have more mobility at the front of the mouth; (b) there is a richer supply of structures for sensory control at anterior vocal tract locations; (c) acoustic-perceptual effects are greater at the front than at the back. The logical product of these factors, however, would be systems composed exclusively of merged or minimally distinct close front vowels; clearly, some force must counteract this trend. Samuels (1972) suggests that a drive to maximize sonority keeps the system's elements in circulation. Close vowels, being relatively low in sonority, tend to fall in order to boost their sonority/contrastiveness, but rise again, as merger with existing open vowels becomes a threat.

The second explanation abstracts away from articulatory issues to focus more narrowly on perceptual and communicative factors. Vowel systems are in this view self-organizing, homeostatic, closed systems in which the preservation of auditory distinctiveness and communicative potential are paramount. A vowel system's geometry emerges from the interplay of several antagonistic pressures: (a) the need to maintain sufficient contrasts for successful communication to take place; (b) a requirement that these contrasts be perceptible to listeners (and crucially learners); and (c) the necessity for a system to maximize the acoustic/perceptual distance between each term in the system, regardless of how many terms the system contains (see e.g., de Boer 2001). Chain shifts (at least those involving push chains) arise from this interaction: if instability is introduced anywhere in the system such that merger is threatened, the system will compensate by moving the vowel that is being encroached upon out of harm's way. Equilibrium is restored when the threat of merger diminishes. The system also seeks to maximize contrast in other ways, e.g., by exaggerating the distance between nucleus and glide in diphthongal reflexes of close vowels, as Stockwell and Minkova (1999) argue for the GVS (see also Labov 1994).

A third approach, which derives most heavily from the neogrammarian and structuralist traditions, stresses systemic configuration, in particular the role of front-back symmetry. Neither articulatory nor perceptual factors are given much consideration here: rather than the communicative needs of speakers and listeners, the system's own requirements instead govern the behavior of its individual constituent elements. In this strongly internalist model, chain shifts are seen as unitary phenomena which, like the GVS, may take centuries to complete, and which to

modern (socio)linguists may appear rather too teleological to be plausible (see *Sociolinguistics and Language Change*). The system is indeed seen as functionally independent of the speakers who use it, the latter being seen as conduits through which changes diffuse when the system seeks to reorganize itself (see Samuels 1972: 42). The speaker-system relationship is always problematic in accounts of sound change, and is clearly a central issue when establishing the validity of any chain shift model. Some associated problems are discussed briefly in the final section.

5. Further Questions

Recent methodological developments have meant that chain shifts can be studied much more objectively than was previously possible. Initial observations were made from fragmentary historical evidence based on orthographic clues, and by comparing the vowel systems of closely related languages and dialects. However, since we usually have no means of verifying data drawn from older written sources, their validity cannot be beyond question. Comparison of languages and dialects is also problematic, in that reconstruction of stages intervening between two varieties and a common ancestor usually necessitates interpolation made in the absence of documentary evidence.

More recent analyses derive from detailed auditory transcriptions of vowel variation in synchronic varieties, and since the groundbreaking work of Labov et al. (1972), have been augmented via instrumental phonetic methods aimed at capturing important acoustic properties of vowel sounds. Vowel quality in such studies is represented by cross-plotting the frequencies in Hertz (or some transform thereof) of the lowest two formants (F1 and F2) of vowel tokens against one another. Chain shifts in progress can be detected by comparing the differences between formant values in samples for multiple speakers, and/or for the same speaker(s) at different times. If the differences between samples affect several vowel categories at once, and do so in some coherent way, the differences may be interpreted as the kind of coordinated change expected when chain shift is taking place.

Much idealization is, however, necessitated by the mapping of continuous, highly variable acoustic data onto the discrete categories they are theorized to express. This is true, for example, of Labov's classification of vowels as [±peripheral], a feature he argues is based on tongue position rather than acoustic criteria, but which is probably at least as difficult to define articulatorily as it is acoustically. Indeed, the emphasis on articulatory and acoustic properties of vowels underpinning much work on chain shifts may be misplaced, in that listeners only have access to auditory representations of the sounds

in question. Warping of acoustic space by the auditory system may mean that purely acoustic representations of vowels cannot unambiguously determine their perceptual values, so it may be rather too simplistic to say that increases or decreases in formant frequency values relative to some putative 'target' or 'prototype' will be perceived as, say, fronting or raising, especially in view of the fact that the auditory system has been demonstrated to utilize a broad range of cues in vowel perception (duration, F0, formant transitions into and out of adjacent consonants, etc.), rather than solely the frequencies of F1 and F2 at the vowel's midpoint. Furthermore, present accounts take a solidly 'bottom-up' (purely signal-based) approach to speech perception, and have little to say about the roles of lexical factors or listener experience in the process by which listeners recognize spoken words (Lindblom 1990, McClelland and Elman 1986).

Despite these and other problems that attend any formulation of a theory of chain shift, the contributions of Labov and his coworkers are absolutely central to our understanding of the phenomenon. Although most research carried out in the area has, understandably, focused upon (North American) English, there is clearly great scope to test the validity and predictive power of Labov's principles on data from other languages. Ultimately, principles of chain shifting would need to be part of a superordinate theory of sound change which accounts for the apparently contradictory processes of both chain shift *and* merger; while system functionality looks to be important from a chain shift point of view, mergers, which are essentially dysfunctional, are—as Labov himself acknowledges—actually more common. At present, we have a powerful set of principles to account for chain shift, but there remain many questions to be answered—not just those concerning the details of how chain shifts operate, but also in terms of the fundamental assumptions upon which much of the current research in the area is built.

Class and Language

F. Gregersen

Class is a sociological concept originating with Marx (see *Marxist Theories of Language*). As such, it implies a conflict-view of society, a view that taken to its linguistic conclusion seems to imply that a continuous linguistic class struggle is characteristic of capitalist society. The concept of linguistic class struggle, however, has hardly played a role in linguistic research; the prevalent use of the concept of class has, rather, been that of a speaker variable within sociolinguistics (see *Sociolinguistics and Language Change*; *Sociology of Language*; *Social Class*).

Two kinds of sociolinguistics, viz. theoretical and empirical sociolinguistics, may be distinguished.

1. Class in Theoretical Sociolinguistics

In theoretical sociolinguistics, the relevant questions pertaining to class language are:

(a) Is there any logical connection between the sociological concept of a class, defined with respect to the conditions of production, power relations (see *Power and Language*), or political consciousness on the one hand and the various levels of language on the other? If so, what are the mediating factors?

(b) How can the effect of class be detected in an individual member's everyday language use?

An attempt to answer such questions may be found in a somewhat difficult book by the Soviet researcher Voloshinov (1973). (Some researchers have tried to identify V. N. Voloshinov (see *Voloshinov, Valentin Nikolavic*) with the literary theoretician M. M. Bakhtin (see *Bakhtin, Mikhail M.*; *Dialogism*) Voloshinov's book *Marxism and the Philosophy of Language* (originally published 1929) is in a sense a classic, but it has not led to the establishment of a research tradition. The book did influence literary stylistics and the study of discourse phenomena such as indirect speech (see *Discourse; Representation*), but it has not been much discussed by sociolinguists. The comprehensive reviews of the field, Fasold (1984, 1989) and Chambers (1995), do not even mention Voloshinov; though Mesthrie et al. (2000) attempt to correct this imbalance.

1.1 Theoretical Sociolinguistics: The Relationship between Class and Language

The specific relationship that Voloshinov sketches takes material existence to be basic and consciousness to be its—though not direct—reflection. The individual's continuous coming to grips with his or her material existence produces a 'world view.' This world view is ideology, and ideology is of central concern for a Marxist theory of language and thus for its recent offsprings, such as critical discourse analysis, as well (see *Marxist Theories of Language; Critical Language Awareness*). Since class is based on differential relationships to the forces of production, the members of a given class share material conditions of existence, and thus to a large extent will produce similar world views. In this theory, the

relationship between class and language is that class, as a convenient shorthand for material conditions, determines language, in that the semantics underlying any particular utterance will be found to vary along class lines. The argument is not easy to follow, but it is suggestive and, what is more important, in the early 2000s it is still the only worthwhile effort to forge a theoretical link between objective social existence and its subjective perception as this results in language use. The mediation between class and language use takes two paths. On the one hand, the class specific culture subsumes certain class specific speech events and in turn specific genres, registers, speech acts, and thus finally specific meanings. On the other, certain common speech events are typically carried out in class specific ways; this too goes for the linguistic hierarchy, thus, for example, creating class specific narratives as well as class specific ways of narrating. Whether this perception is, in fact, too abstract to be related to everyday language use depends on the place assigned to semantics in one's theory of language. If what people (may) mean determines what they (may) say, chances are that semantics determines language use. The functional systemic theory of Michael Halliday (see *Halliday, Michael Alexander Kirkwood*) is based on a view of language which facilitates this line of thinking (cf. below on semantic variables).

2. Empirical Sociolinguistics: Studies of Class Language

Much more frequent and well-known are empirical studies of the relationship between specific linguistic variables and class as a speaker variable.

2.1 Problems with Class as a Speaker Variable

It is not that simple to decide which persons belong to which class. First of all, the abstract Marxist concept has to be operationalized.

'Operationalizations' are helpful only insofar as they point to easily detectable features of a person's social background. There is thus a very real danger that operationalization may take the place of analysis. In a penetrating study of the class concept used by sociolinguists, Glyn Williams (see *Williams, Glyn*) argues convincingly that the structural functionalist theory of Talcott Parsons has been taken as the more or less conscious point of departure for any operationalization. The normal operationalizations of class revolve around power, education, income, and type of work. For instance, William Labov (see *Labov, William*), in his ground-breaking study of the New York Lower East Side speech community (Labov 1966), used the last three latter factors in order to produce a composite index. This index was scalable, and thus the number of social strata could be arbitrarily defined. In fact, Labov used both a six-strata and a nine-strata measure of social back-

ground. Obviously, class in this tradition is no longer a Marxist concept, since the difference between classes is reduced to being quantitative instead of qualitative.

Class as a measure of social background should be used with caution. First, it is not valid in non-industrialized societies, and, to say the least, it is also very hard to apply in nonindustrialized sectors of otherwise industrialized societies. This is the reason why different measures of social position have been brought into play within social dialectology and the sociolinguistics of the Third World (see *Dialect and Dialectology*; *Linguistic Imperialism*).

Second, class tends to be a synchronic measure, unless one differentiates, for example, between new-comers to a class and those born into it, or one takes into account the position of the family through generations.

Third, class as a concept does not work well with women, children, and youngsters who have not yet found a permanent position. Since this excludes quite a significant proportion of a given population from the analysis, various other measures of social background have been introduced. Most importantly, there is a growing uneasiness about purely quantitative measures of social background. Comparable trends are found within the rest of the social sciences, as witness the success of network analysis, anthropological analyses of social structure, and life-history approaches.

2.2 Class and Field Methods

All of this amounts to an enormous challenge to sociolinguistics.

Sociolinguistics is concerned with the relationship between society and the social characteristics of individuals on the one hand and language and language use on the other. This field can only be studied empirically if it is possible to find linguistic data produced by persons whose own social background is known. Since Labov's early studies, the universally used method of collecting such linguistic data has been the sociolinguistic interview (see *Sociolinguistic Variation*; *Field Methods in Modern Dialect and Variation Studies*).

A sociolinguistic interview consists of a semistructured conversation between a fieldworker and an informant. The job of the interviewer is to lead the informant to produce speech of various kinds, speech belonging to two or more different styles. The interview is a useful way of collecting linguistic data, but it must be remembered that this is not a way of getting to know the total cultural background and everyday practice of informants.

Obviously, one cannot interview 'the' working class or 'the' middle class; one must limit oneself to interviewing individual members of those classes. Since interviewing is not a 'natural' speech event for

anyone, this calls for an analysis of what is for any given class the most obvious equivalent of the sociolinguistic interview. This, however, can only be done if one has recourse to data concerning the total repertoire of speech events. It is very likely that such repertoires will manifest significant differences, when analyzed precisely from the point of view of class. Class is supposedly a cultural concept in addition to being a sociological one, or rather, the sociological fact of class has definite cultural consequences.

2.3 Which Classes?

There is an interesting difference between sociological models that allow any member of a given society to be classified and models which take certain characteristics to be decisive for the allocation of an individual to a specific class, thus allowing for unclassified persons. The Marxist conception of two opposing classes, one defined as having power over the forces of production (the capitalists), and the other as being exploited by the first mentioned class, has never been taken as a relevant starting point for empirical studies. The two classes opposed have universally been (some variant of) the middle class (MC) and (some variant of) the working class (WC). Since these two classes are not defined according to strictly Marxist criteria, at least in the classical sense, there is a choice as to whether they are seen as differing from each other quantitatively or qualitatively. In most industrialized countries, the middle-class member has an academic education and holds higher-level jobs. The income is at least above the average. The typical WC member, on the other hand, has less education, less power in his job, and earns less than the typical MC member. (Obviously, these are only statistically valid characteristics; any one member of the MC or the WC may deviate in one or more respects.)

Originating with Labov, a further distinction may be made within the MC, viz. between the lower middle class and the 'real' middle class. When doing quantitative studies, this distinction may be important, since there is much evidence to confirm that these two sections of the MC differ linguistically (see Sect. 2.6).

2.4 Quantitative Studies of Class and Language

Quantitative studies feature a collection of individuals distributed on a number of background characteristics so as to make up various mini-populations, for example, the working class versus the middle class, or the lower working class versus the working class proper and the higher working class, etc.

The linguistic features to be studied here are known as 'sociolinguistic variables.' The definition of a sociolinguistic variable has been a matter of discussion. Previously, the state of the art dictated that sociolinguistic variables were almost all phonetic ones, whereas in the 1990s the continuation of the work of Bernstein (see *Bernstein, Basil*) by R. Hasan has been influential in shifting the focus to semantic variables (see Hasan 1989). Phonetic variables have, however, been by far the best-studied (see *Socio-phonetics; Sociolinguistic Variation*).

The results of these studies have been summarized by Fasold (1989: 223ff.) and Chambers (1995: 34ff.) and may be found in any manual of sociolinguistics. A prominent feature of a number of studies is that linguistic stratification can be shown to parallel exactly social stratification. Thus, a result which is found repeatedly is that certain sociolinguistic variables seem to ape social structure. If an individual belongs to a specific class, that individual's use of the variable is statistically predictable.

This has led to speculations why this is so. On the one hand, the result is somewhat tedious; one does not obtain any new information, since the social stratification was known from the start. On the other hand, the very tedious repetition of the result at least demonstrates that language use is patterned sociologically. This is news to the public at large, since it makes discussions of the correct pronunciation or the right way of spelling rather more complex. If pronunciations vary statistically with class, there cannot be any one correct pronunciation that is neutral as to class membership.

2.5 Class Language and Norms

Most European countries have a long tradition of language planning (Joseph 1987). The ideal which most planning agencies have striven towards realizing has never been defined in class terms. It is evident, however, that the ideal norm has been modeled on the speech of the leading classes in society. Since the leading classes have a way of promoting their own culture or their own ideas as natural, it should not come as a surprise that the linguistic norm has been thought to be natural as well. Sociolinguistic results have at least had the beneficial effect of revealing the true class character of any norm based on authentic speech.

2.6 Class and Style: Hypercorrection

It is the purpose of the sociolinguistic interview to provoke different speech styles. This is done by manipulating the conversation in various ways (see *Manipulation; Conversation Analysis*); the crucial fact is, however, that style variation in itself can only be explained in terms of a conflict between the norms of the various subgroups within a speech community. Taken universally, the result of sociolinguistic studies is that individuals from all conceivable strata vary individually in important ways. This intraindividual variation is called 'style variation.' The relationship

between class-determined variation and style variation is normally that speakers converge more, the more formal the style. There seems to be general agreement on the part of the speakers about what is most appropriate in formal styles, just as there seems to be a general tendency to differ more, the more casual the style. This has been taken to mean that a defining characteristic of a speech community is the agreement on what should be counted as worth imitating; as a definition, this is hardly valid. A competing explanation is that the more formal situations are regulated by the norm either directly (schools, public service, (state) television, etc.) or by association with people representing the norm. And the norm is—naturally—more akin to (if not identical with) the speech of the higher social classes.

The perception of the speech of the higher social classes as socially attractive is brought out very nicely in the phenomenon of hypercorrection. In Labov's studies, the lower middle class had a curious 'cross-over' pattern in the more formal speech styles, that is, they produced more higher-class forms than the 'real' MC members did themselves. This phenomenon is called 'hypercorrection.' The lower middle class correctly perceives that the real MC members differ from the rest in that they produce more (or less) of certain (mostly phonetic) sociolinguistic variables; consequently, the lower middle class members produce as many (or as few) as possible of these sociophonetic variables in the situations that call for prestige forms. In this, they succeed too well, only to succeed in revealing their belonging to the lower middle class (see *Sociolinguistic Variation*).

The importance of the phenomenon of hypercorrection for the study of class language is that it shows convincingly that the link between class and sociophonetic variables is much more indirect than might be suspected, if one just looks at parallel stratification patterns.

Dialect and Dialectology

S. Romaine

Dialectology is a long-established branch of linguistics: the existence of geographical diversity was among the first observations made by the Greeks. Dialectology determined to a great extent the nature of scientific research into language in the nineteenth century. The investigation of local dialects was seen as a way to recapture linguistic history and to provide the missing links for comparative historical reconstruction, the primary enterprise of linguistics at that time. It was believed that dialects preserved older speech patterns in pure form. Research into dialects was also spurred on by the Romantic movement, which fostered a more general interest in folklore. Robert Burns and many other poets chose to write in their dialects rather than in the standard literary language.

1. The Term 'Dialect'

In both its traditional and modern sense dialectology has to do with the origins and distribution of dialects. The term 'dialect' has generally been used to refer to a subordinate variety of a language, such as English, which has many dialects. A regional dialect is a language variety associated with a place, such as the Yorkshire dialect in England or the Bavarian dialect in Germany. Dialects of a language tend to differ more from one another the more remote they are from one another geographically. In this respect

dialectology has to do with boundaries, which often coincide with geographical features such as rivers and mountains. Boundaries are, however, often of a social nature, e.g., between different social class groups, 'social dialects' (see *Language in Society: Overview*).

The term dialect also has historical connotations. Historical linguists, for instance, speak of the Germanic dialects, by which they mean the ancestors of language varieties now recognized as modern Germanic languages, such as English, Dutch, and German. The entities labeled 'English language' or 'Flemish dialect' are not, however, discrete. Any variety is part of a continuum in social and geographical space and time. The discontinuities that do occur, however, often reflect geographical and social boundaries and weaknesses in communication networks (see *Language*).

Some classic cases of related dialects are the West Romance and Germanic dialect continua. The West Romance dialect continuum stretches through rural communities from the Atlantic coast of France through Italy, Spain, and Portugal. Mutual intelligibility exists between adjacent villages, although speakers of the standard varieties of French, Italian, Spanish, and Portuguese find one another mutually unintelligible to varying degrees. Similarly, the Germanic dialect continuum connects a series of historically related varieties that differ from one another with respect to one or more features.

2. The Term 'A Language'

The dividing line between the languages called Dutch and German is linguistically arbitrary but politically and culturally relevant. Max Weinreich's often quoted dictum, 'a language is a dialect with an army and a navy,' attests the importance of political power and the sovereignty of a nation-state in the recognition of a variety as a language rather than a dialect. Situations in which there is widespread agreement as to what constitutes a language arise through the interaction of social, political, psychological, and historical factors, and not any inherent properties of the varieties concerned.

Certain varieties of the West Germanic dialect continuum are considered to be dialects of Dutch and others, dialects of German because of the relationship these varieties have to their respective standard languages. The process of standardization is connected with a number of sociohistorical factors such as literacy, nationalism, and cultural and ethnic identity. It results in the selection and fixing of a uniform norm of usage, which is promoted in dictionaries, grammars, and teaching. A standard language is a variety that has been deliberately codified so that it varies minimally in linguistic form but is maximally elaborated in function.

Chambers and Trudgill (1998) distinguish between autonomous and heteronomous speech varieties as alternative labels to language and dialect. The Dutch dialects are dependent on or heteronomous with respect to standard Dutch, German dialects with standard German. This means that speakers of German are taught German in school. They look to standard German as a reference point. The term 'language' is employed for a variety that is autonomous together with all those varieties with which it is heteronomous.

Because heteronomy and autonomy reflect political and cultural rather than purely linguistic factors, they can change. Often through political developments formerly heteronomous varieties can achieve autonomy, as in the case of Afrikaans in South Africa, which was standardized in the 1920s and recognized as a language and not a dialect of Dutch. Conversely, autonomous varieties may lose their autonomy, as Scots did when it ceased to function as the language of the Scottish court after the Union of Crowns in 1603.

3. Differences between Dialects

Some linguists make a further distinction between accent and dialect. An accent consists of a way of pronouncing a variety (see *Accent*). A dialect, however, varies from other dialects of the same language simultaneously on at least three levels of organization: pronunciation, grammar or syntax, and vocabulary. Thus, educated speakers of American English and British English can be regarded as using dialects of the same language because differences of these three kinds exist between them. In practice, however, speakers of the two varieties share a common grammar and differ from each other more in terms of vocabulary and pronunciation. Some examples of these differences are illustrated in Table 1.

4. Dialect Geography

The beginnings of traditional dialect geography are found in the work of Georg Wenker who prepared 40 sentences designed to yield information on dialect differences in German, e.g., *Im Winter fliegen die trocknen Blätter herum* 'In the winter the

Table 1. Some differences between American and British English

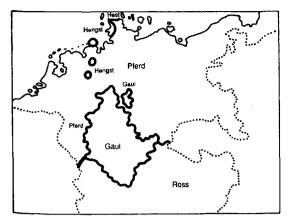
	American	British
Pronunciation	*ate /eit/* (rhymes with *mate*)	/ɛt/ (RP; see *Accent*) (rhymes with *met*)
Grammar/ Syntax	*Jane had gotten used to it.*	*Jane had got used to it.* (pp of *get*)
Vocabulary	*Sam took the elevator rather than the stairs.*	*Sam took the lift rather than the stairs.*


Figure 1. Dialect map for the names given to 'horse' in Germany.

dry leaves fly around' (see *Wenker, Georg*). From 1876 onwards he sent these out to schoolteachers in numerous localities. The teachers were asked to transcribe the sentences using the speech characteristics of the area. The material was then mapped and the characteristic features of dialects were plotted by the geographic location of their occurrence. The linguistic boundaries between varieties are called 'isoglosses.'

Major dialect boundaries are often characterized by a bundle of isoglosses. Figure 1 shows one of the maps produced by this type of investigation. It displays the names given to 'horse' in Germany. The main terms used are *Pferd* (which has become standard High German), *Gaul*, and *Ross. Hengst* is also used in the northwest and *Hest*, in the north. Most dialect investigations presented their results in linguistic atlases which provided a geographical representation of linguistic facts. Because such maps were difficult and expensive to produce, many of the results of dialect investigations took decades to publish, and some such as Wenker's never appeared in published form.

Wenker's methods had some other disadvantages, a major one being the idiosyncrasies in the transcribing procedures used by the schoolteachers. His sentences were also designed to elicit mainly phonological (and lexical) rather than syntactic or morphological variation. The Germans, however, remain a major influence on dialectology, especially in the English-speaking world. Much of the early work on Scottish dialects was done by Germans and most surveys owe much to the methodology of the Germans.

In France, Jules Gilliéron (see *Gilliéron, Jules*) drew on the work of Wenker and trained one fieldworker, Edmont, to collect the material for the French linguistic atlas which was published in

entirety in 1910. Edmont cycled to 639 locations in France, where he personally gathered material by direct questioning.

The next major dialectological investigation took place in the United States, where the methods of Wenker, Gilliéron, and Jaberg and Jud (1928–40) were adapted (see *Jaberg, Karl*). Hans Kurath (see *Kurath, Hans*) attempted to overcome some of the shortcomings in earlier European work by paying more attention to the selection and training of fieldworkers, as well as the selection of informants and localities, and the preparation of a questionnaire.

The first large-scale dialect study in the United States produced the *Linguistic Atlas of New England* (referred to by the acronym LANE), a survey of 213 rural and urban communities. Subsequent atlases such as PEAS (*Pronunciation of English in the Atlantic States*), LAGS (*Linguistic Atlas of the Gulf States*), LAUM (*Linguistic Atlas of the Upper Midwest*) dealt with other regions such as the Atlantic States. Large-scale dialect geography began in England slightly later with Orton's survey of 300 small villages in England and the Isle of Man.

5. Dialect Patterns

The availability of the American and English atlases allowed dialect patterns in the United States and Britain to be compared. American isoglosses rarely terminate abruptly, which indicates a basic difference between the structure of dialect differentiation in the two countries. The American population has always been more mobile both socially and geographically so that the conditions for the development and maintenance of local dialects were never met to the same extent in the United States as they were in Europe.

Nevertheless, the findings of American dialectology dispelled the myth that there was a general American speech. Instead there were a number of speech areas, each of which was divided into a number of smaller subareas. Each major region constituted a unity and had its own regional standard of pronunciation. In England, however, the most local dialects were associated with the groups at the lower end of the social hierarchy, while those at the top spoke RP (Received Pronunciation), which showed no trace of regionalisms. In the eastern United States three major dialects were identified: North (including New England and the Hudson Valley); Midland (Pennsylvania and the Alleghenies); and South (Chesapeake Bay, Virginia Piedmont, and the Carolinas). Each major area is enclosed by a large number of isoglosses representing differences in lexis, grammar and phonology (see Fig. 2).

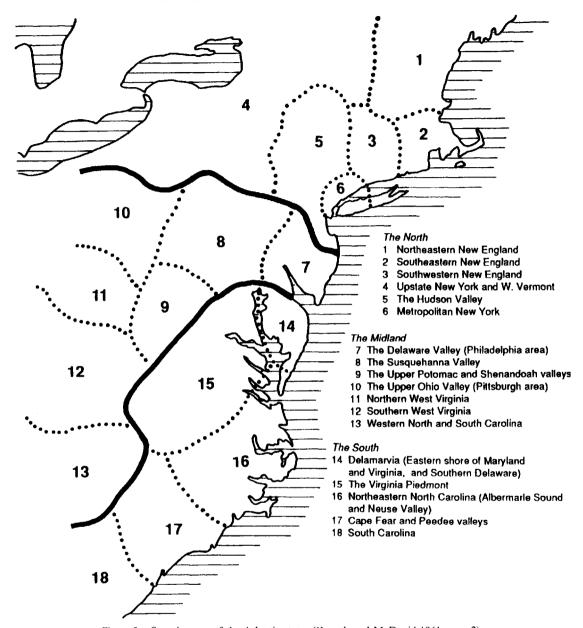
It also became possible to trace the transference of patterns from Britain to the United States. Before Kurath's work, the prevailing opinion was that American English was essentially Southern Standard English of the seventeenth and eighteenth centuries


Figure 2. Speech areas of the Atlantic states (Kurath and McDavid 1961: map 2).

as modified locally. Kurath, however, demonstrated that most of the dialect differences in the United States have their basis partly in regional varieties of British English which earlier settlers brought with them. In Britain, for instance, the words *brook, burn*, and *beck* show broad regional distribution. *Brook* is dominant throughout the Midlands and into the south; *beck* is found in the area of former Danish settlement, and *burn* (from Scots) extends from Scotland into the border counties of northern England. *Brook* was transported across the ocean and, although it had strong regional ties in England, it was the form accepted as standard. Its rival regional variants were left behind and two new

313

regional forms developed in the United States, *run* (found in the Midland dialect) and *branch* (Southern). The form *brook* is northern. Thus, an item showing a broad regional pattern in England became narrowly local in the United States.

There is linguistic evidence for a historical connection between American speech of the north and west and that of northern England, and to some extent that of the American south and the pronunciation of southern England. These linguistic similarities are well supported by the history of American colonization, patterns of westward movement, and later immigration. This is illustrated in the distribution for postvocalic /r/, as in *cart, barn*, etc.

In Britain the distribution of postvocalic /r/ based on Orton's (1962) *Survey of English Dialects* shows that nonrhotic dialects were the result of an historical innovation which began somewhere in the east or center of England before spreading northwards. Before Irish immigration to the United States, the population of eastern New England came from the southeastern counties of England, where varieties closest to RP are spoken. RP lacks postvocalic /r/. Western New England, on the other hand, had a large number of Scots–Irish immigrants, whose dialects had postvocalic /r/. The Virginia tidewater region and the coastal south were also settled largely by the Scots–Irish. Thus, nonrhotic speech (i.e., without postvocalic /r/) was typical of coastal areas and rhotic speech of inland areas. Hence there are clusters of nonrhotic speech around the major ports of Boston, New York, and Charlestown. This was true not only for reasons of settlement pattern, but for cultural reasons. The coastal areas which had nonrhotic speech kept it because they were in touch with English prestige patterns of speaking. The population of the Mid-Atlantic states was mixed. Philadelphia was an exception to the port pattern of nonrhotic speech because of Quaker settlement. The Quakers attracted immigrants from all parts of Britain and the rest of Europe. They maintained less trade with Britain and sent fewer children back to English universities. Since World War II, rhotic speech has become more prestigious in the United States.

6. Dialects and Sound Change

Since its beginnings in the nineteenth century dialectology has contributed both theory and methods to linguistics. The early work done in Germany and France provided a basis for interpreting the linguistic significance of the patterning of isoglosses. Most importantly, however, it seriously challenged prevailing views of sound change. Ironically, early studies of dialects had set out to support the neogrammarian hypothesis that sound change took place according to sound laws that admitted no exceptions. In the case of the second Germanic sound shift, an important test case, neogrammarian principles would predict that all late Proto–Germanic instances of /k/ would become /x/ all over the High German territory.

It was Georg Wenker, who showed that the second Germanic sound shift had exceptions. This can be seen in the set of isoglosses in Fig. 3, which separates Low from High German. The isoglosses run from east to west across Germany (slightly north of Berlin) and the Netherlands. The features comprising the isoglosses include the pronunciation of final consonants such as /p/, /t/, and /k/ in words such as *dorp/dorf* ('village'), *dat/das* ('that,' 'the'), and *ik/ich* ('I'). The first member of each of these pairs is the Low German variant, as found in modern standard Dutch; the second is the High German variant, as found in modern standard German. The isoglosses for *machen* cross the Rhein near Benrath, slightly south of the point where the isogloss for *ich* crosses the Rhein at Urdingen. This is one of the most important dialect boundaries in German, the Benrath–Urdingen line, which divides Low from High German. As one moves eastward, the isoglosses for the two words and also for *dat/das, dorp/dorf*, etc., are the same. The point at which the isoglosses meet the Rhine is marked by a fanning out of the isoglosses. For this reason the isogloss has been called the Rhenish fan. In villages along this area speakers may have some Low German features and some High German features, for example, both *dat* and *dorf*.

In practice, most changes are not completely regular because all innovations diffuse through time and space at different rates. In fact, many inconsistencies such as these were found, which illustrated the complexity of dialect differentiation and the need to invoke explanations from external historical factors.

The explanation for the pattern of variation found in the Rhenish fan comes from cultural history. The Benrath line corresponds to the extent of influence of the city of Cologne from the thirteenth century, and the Urdingen line to its influence from the sixteenth century. The forms for *machen* were fixed at an earlier date than those for *ich*. The differences in the isoglosses can be accounted for by assuming that a sound change had taken place in southern Germany and spread northward. The extent of spread of this innovation was determined by both geographical and social factors. Among the latter was the social prestige of the urban speakers who used the new forms.

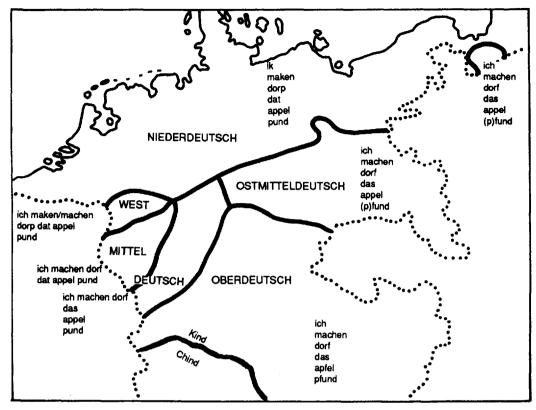
Such areas of prestige form focal points which transmit innovations into the surrounding hinterland. At the limits or peripheries of such centers of diffusion we find transition areas which typically show characteristics of two neighboring


Figure 3. Distribution of isoglosses in Germany and the Netherlands.

focal areas. Beyond these are relic areas which are removed from the effect of expanding isoglosses. Relic areas are generally found in places that are not so easily accessible. Prestige innovations and settlement patterns can often be traced by examining isoglosses and place names. Linguistic innovations often hop from one urban center to another (compare the American port cities pattern of rhotic speech) and only later spread out to rural areas in between.

The Rhenish fan is an important isogloss not just in dialectology, but also for the questions it raised about change for historical linguistics more generally. Table 2, which is a schematized description of the isogloss bundle, shows a step-like patterning of the isoglosses between north and south German in geographical space. This model suggests that the new pronunciations gained in frequency while both shifted and unshifted forms coexisted. The numbers 1 to 7 can be thought of as different dialects. Stage 1 represents a dialect which has undergone no change and stage 7 shows the completed change. Dialects 2 through 6 show intermediate stages in the shift. For

all practical purposes, the beginning and end stages show that the net effect of the change is as if it had applied uniformly and simultaneously to all dialects.

Table 2 gives a picture of the transition phase and the line drawn through it indicates the trajectory of the change as it spreads from dialect to dialect and from one lexical item to another. In the 1970s theoretical discussions of this pattern of change referred to it as 'lexical diffusion' (see Chen and Wang 1975). On the basis of evidence from patterns such as these, Gilliéron proposed, instead of regular sound change that *chaque mot a son histoire* ('Each word has its own history').

Late twentieth-century work on dialect variation has attempted to formalize this view of change which assumes that innovations spread in waves. Models proposed by Bailey (1973) and others predict that a change moves through the grammar (in the case of the Germanic sound shift, a rule which changes /p/ to /f/, etc.), affecting one environment in one (iso) lect at a time. Bailey has backformed the term 'lect' from 'dialect' as a more neutral term for a clustering of

Table 2. Implicational scale of isoglosses between Low and High German consonant shift /p t k/ → /(p)f s x/.

Dialects	Lexical items	ich	machen	dorf	das	apfel	pfund

German	5.	+	+	+	+	−	−
	6.	+	+	+	+	+	−
High German	7.	+	+	+	+	+	+

linguistic features. Many linguists now prefer the term 'variety' or 'lect' to avoid the sometimes pejorative connotations of the term 'dialect'.

Table 3 shows an implicational scale for the sound shift in which lects and lexical items are implicationally ordered. Environments either have a rule (+) or they don't (−), while others are variable, i.e., in the process of transition from plus to minus. Since isolects are located in both space and time in such a model, they participate either earlier or later in an incipient rule change at any given point in the spatiotemporal continuum. It is possible to incorporate many lects into a polylectal or panlectal grammar, which would consist of all possible sets of rules for an arbitrarily limited area in space and time. Bailey and others maintain that such models are also psychologically real because speakers have polylectal competence rather than just competence in their own lect.

Linguists have also made predictions about the direction and rate of rule spread based on considerations such as markedness. Bailey claims that the farther a rule travels from its origin, the fewer will be the environments above it on an implicational scale. Change begins in the most heavily weighted environment and works its way through the grammar by spreading through successively less heavily weighted environments. This pattern of spread has the consequence that rules generalize in time, but seem to become less general in space because the temporally earlier changes move farther than the later ones. Only linguistic factors count in the Baileyan model towards an explanation of variation. Bailey claims that, since grammars are ongoing entities in time, time alone accounts not only for spatial patterns of variation, but for age, social class, and stylistic patterns of variation.

7. Theoretical Underpinnings

A dialect continuum can be social rather than geographical. Implicational scales and polylectal grammars have also been used to model post-Creole continua. A good example is found in Jamaica, where at one time those at the top of the social scale, the British, spoke English, while those at the bottom spoke Jamaican Creole. Over time the gap between the two has been filled by a range of varieties that are either more like the Creole or more like English. Most speakers use several varieties that span a range on this post-Creole continuum and shift among them according to context or addressee. Any division of the Jamaican social dialect continuum into English versus Jamaican Creole would be linguistically as

316

arbitrary as dividing the Germanic dialect continuum into Dutch and German. There is no social, political, or geographical reason for saying that English begins at one particular point and Jamaican Creole at another.

Other attempts to provide dialectology with theoretical underpinnings can be found in Weinreich (1968), who proposed a structuralist dialectology (see *Weinreich, Uriel*). Most of the differences studied by dialectologists are lexical, and concern the different names people in different areas have for things. Thus, in the north of England the term *stee* refers to the same item which *ladder* refers to in the south of England. Such cases are dealing with the mapping of different names onto the same referent. The item itself serves as a reference point. The maps produced from such studies are known as 'onomasiological' maps. American dialect geography has dealt exclusively with onomasiology. The Survey of English dialects is also largely concerned with differences in naming practices. However, the words collected from such an investigation will not necessarily be etymologically connected, e.g., *spade, shovel* and *spit*, or *stee* and *ladder*.

It is possible to start from names and to look at how their meanings vary. In this case the point of reference is the word itself which may have more than one meaning. Thus, in Texas *hydrant* refers to an outdoor 'faucet' or 'tap,' while *fire plug* refers to what in most other areas of the United States is known as a (*fire*) *hydrant*. Maps showing distributions of meanings are called semasiological. Figure 4 is a semasiological map depicting the meaning of *shtul* in East European Yiddish. There are two major dialect areas, A, where *shtul* means 'chair' and B, where it means 'easychair.' Each semasiological map then gives rise to as many onomasiological maps as the number of dialect areas it contains and vice versa, i.e., one has to chart the terms for 'easychair' in dialect A and for 'chair' in dialect B. This can be seen in Fig. 5. In dialect A *benkl* is the term used to refer to a 'little bench,' while in dialect B it means a plain 'seat.' In dialect A the borrowed term *fotel* is used to mean 'easychair.'

It is not sufficient to say that *shtul* in dialect A of Yiddish is the same as in dialect B, if in A it is part of a three-way opposition in meaning but only a two-way one in B—similarly for phonology. As in Bailey's polylectal grammar, this approach gave dialectology a basis for the study of dialects with reference to internal linguistic patterning. A diasystem was constructed without consideration of geographical, or cultural factors. It was primarily a linguistic method of analysis.

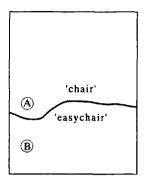
An example can be taken from the Linguistic Survey of Scotland, which was one of the first dialect investigations to be influenced by Weinreich's ideas about structural dialectology. It also drew on the


Figure 4. A semasiological map of the meaning of *shtul* in East European Yiddish (Weinreich 1968: 318).

polysystemic approach of Firth (see *Firth, J. R.*), which viewed language or parts of language as systems. The Linguistic Survey of Scotland examined the distribution of vowel contrasts in eleven different environments or subsystems based primarily on place of articulation, e.g., before /r/, before /t/, etc. Researchers identified a basic vowel diasystem consisting of eight units whose phonetic realization and distribution in lexical items varied from dialect to dialect. Figure 6 shows this system, where E, Y, and A refer to additions which may occur at the points indicated. The unit E may contrast with the front series in terms of length or quality or both, while Y may contrast with /i/ and the front vowels in rounding. Two modifications may take place in the low, back area: A_1 represents a vowel which may contrast with /a/ by being further back or rounded or both; A_2 refers to a rounded vowel between A and /o/. Systems are classified in two ways, in terms of number of units, i.e., inventory; and in terms of the internal arrangement of contrast in the system.

The advantage of this approach is that it reveals phonological similarity between dialects which might

317

be otherwise overlooked since comparison at the phonetic level tends to emphasize differences. This method can also be used to generate testable hypotheses about the types of systems likely to be found. The basic system plus various additions yields 12 theoretical possibilities, two of which have not been discovered in investigations so far, i.e., the basic system plus E and the basic system plus E and Y.

Figure 7 shows how the various vowel systems are distributed geographically. The maximal 12-vowel system occurs in three widely separated areas: Shetland; south Kincardineshire, north Angus, east Perthshire; and the extreme southwest. This similarity may reflect the historical fact that many of the Scots who settled Shetland came from the metropolitan area of Fife and the Lothians. Although the 12-vowel system is no longer found in the latter area, it

still occurs along the northern periphery. This suggests that the 12-vowel system is a survival, and that sixteenth-century Scots may have had such a system. Its occurrence in Galloway also supports this hypothesis since Gaelic was replaced there at around the same time as Norn (a variety of Norwegian) was in Shetland.

The structuralist model provided a basis for a generative interpretation of dialect variation (see, for example, Newton 1972). If a diaphonemic inventory is a composite of all the individual inventories of dialects which comprise a language, then it is possible to relate all dialects directly to a single underlying diaphonemic system on the basis of which dialects may be compared as to the number, scope, order, and form of rules needed to derive their distinctive characteristics.

8. Envoi

Some linguists have been critical of dialectology because it is biased towards rural speech of elderly informants and thus does not provide any knowledge of how the majority of people residing in urban areas speak. Dialect surveys have also for the most part relied on individuals, generally men, as the source of data for a particular area (see, however, Kurath

318

1939). Traditional dialectology was often seen as a rescue operation to record traditional forms of speech before they died out. Dialects are not in principle always more archaic nor is there any evidence to suggest that dialect speakers are progressively adopting more standard forms of speech. Although dialects do often preserve forms which were standard at a previous stage and have since been superseded, in some cases they innovate in different directions from the standard. Dialect surveys have been started in new areas such as Australia (Bryant 1991) and the more general study of language varieties has taken a central place in modern linguistics. The high point of twentieth-century dialectology is the Atlas of North American English, combining computer generated maps with modern field methods (Labov, Ash, and Bober, in press; see *The Atlas of North American English: Methods and Findings*).

Dialect Humor

M. L. Apte

The basis of dialect humor is speech variation in a community. Wherever such variation exists there is a potential for dialect humor, a phenomenon in which one or more specific speech varieties become the target of fun and/or ridicule. Jokes, dialect stories, and the exaggerated imitation of the phonological and grammatical characteristics of the speech of a specific geographical community or of a certain social class of people constitute dialect humor. Language and speech, in short, becomes the topic of this type of humor.

1. What Constitutes a Dialect?

The term 'dialect' (see *Dialect and Dialectology*) has generally been used in linguistics to refer to varieties of speech based on geographical location and/or social background. It is used in contrast to the term 'language.' If a language is spoken over a large territory and by a substantial number of people, there exist phonological, grammatical, and lexical differences among its speakers. The reason for this is that frequent communication between each and every one of the speakers, which would considerably reduce any structural differences, is not feasible. Rather, there are concentrated networks of communication in villages, towns, subregions, and cities, as well as among people with similar subcultural backgrounds, occupations, or socioeconomic conditions. It is important to note however, that speech differences do not always hinder communication across geographical or social groups within a linguistic community.

While linguists, since the late 1970s, have used the term 'speech variety' instead of the term 'dialect' to describe the diverse patterns of structure and usage that may occur in a society, lay persons often still describe such speech varieties as 'dialects.' The term carries a pejorative connotation because of the assumption that people who speak a dialect have not been exposed to the influence of the cultural center of a society and its prestigious speech patterns. They are not upwardly mobile and continue to maintain their subregional or low class identity. Linguists use the 'speech variety' primarily to avoid the negative connotations and value judgements associated with the term 'dialect.'

Linguists have also found that in large linguistic territories, especially if they are nation-states, there generally exists a cultural and/or political center—almost always a region or a city—and the speech of its inhabitants is usually considered the most prestigious. This speech variety is used for administrative functions, as the medium of instruction, and also in mass media. Generally, such a speech variety is identified as the 'standard' and for foreigners, as well as many people outside the political center, it is equated with the language of the region.

2. Attitudes towards Dialect Speakers

People who speak the standard (see *Standardization*) variety of a language often find the speech patterns of people from faraway regions or at the lowest stratum of society 'strange,' and these patterns may become the topic of humor. Those who make fun of such speech generally find one or more characteristics of it inherently amusing. It could be, for instance, an unusual pronunciation, the use of unfamiliar words, nasalized speech, peculiar phrases, or the overall slowness of speech. These and other such linguistic features are then mockingly imitated in an exaggerated manner in order to generate humor. It is this kind of humor that is generally labeled 'dialect humor.' In those linguistic communities where the speech variation is considerable, there is much more likelihood of one or two dialects being made fun of because of their perceived low prestige.

However, any analysis of dialect humor will inevitably lead to this question: Is mere speech difference, no matter how extreme it may be, sufficient to make certain groups of people become the butt of humor or do other factors also play a role? It appears that underlying dialect humor are certain attitudes on the part of those who practice it. The joke-tellers generally look down upon those whose speech they make fun of.

The attitude of those who engage in dialect humor is one of disdain towards their target. The speech being made fun of is considered 'inferior,' 'crude,' or 'primitive' and its characteristics are often attributed to backwardness, stupidity, and other negative qualities. If the speech to be made fun of is marked by slowness of tempo, long drawn out vowels, or slurred consonants, it is assumed that this is due to the overall slow-wittedness of its speakers. Once created, such stereotypes are difficult to get rid of even if the gross generalizations on which they are based are false and the associations made between speech and mental ability are invalid, which they are.

Dialect humor becomes 'accent humor' (see *Accent*) when the target speech variety is caricatured through exaggerated imitation, especially of easily noticeable features such as tone, inflection, or choice of words. It should be noted that the objects of accent humor are not always speakers from a region remote from the cultural and political center or of the lowest socioeconomic class. They could very well be the elites who speak the standard variety. The target of accent humor can also be a foreign language. Therefore, dialect humor can be considered one type of accent humor though frequently the targets of accent humor are dialects.

3. Universality of Dialect Humor

Dialect humor appears to be universal. Davies (1990: 52–3) provides a list of countries in which specific dialects and languages are the object of jokes and those who speak these are perceived to be stupid, ignorant, or inept. The following are some speech varieties which have been the target of dialect humor.

In the USA, the Southern dialect and the Brooklyn and the Boston speech varieties have been the targets of dialect humor. The Southern speech variety has been a particularly popular target as evidenced by the existence of many books purportedly teaching non-Southerners how to speak the Southern dialect (Dwyer 1971, Mitchell 1976, Wilder 1977). In England, the Cockney dialect of London has been the target of dialect humor. In Italy, southern Italian dialects such as Neopolitan or Sicilian are the objects of such humor. In North India the Hindi spoken by Panjabi speakers in New Delhi has been similarly mocked. In the Marathi-speaking region of Western India a coastal dialect known as 'Malvani' has been the object of dialect humor. Entire comedies have been written in this dialect by several playwrights and they have been enormously successful. From the same coastal region, the excessively nasalized speech of the Brahmans, traditionally the highest caste in the social hierarchy, has been made fun of.

Because a particular speech variety or language is associated with a specific group, dialect and/or language can be part of ethnic, religious, regional, political, or social identity. Therefore, dialect humor should be considered as a subcategory of ethnic humor (see *Ethnicity and Language*). Any time a particular group is identified by its language or speech variety, such an association leads to the development of its linguistic stereotype.

320

Although much dialect and accent humor is verbal, it has been represented in print, resulting in the publication of dialect-joke-and-story collections of which many copies have been sold. In English and in many other languages, techniques have been developed for transcribing dialect humor and conventions have been established to represent the speech peculiarities. These conventions taken together can be called 'eye dialect' (Falk 1978: 295), a term used to designate a technique in which spelling differences represent the target speech variety. For example, the inability of some dialect speakers of American and British English to pronounce the dental fricative consonants and their substitution by the dental stops is indicated by the substitution of 't' and 'd' for 'th' and 'dh' in conventional spelling of such speech so that words such as 'this' and 'that' are written as 'dis' and 'dat' respectively. The final 'g' consonant of words that end in 'ing' is often dropped in uneducated speech. This is indicated in the written version by doing the same so that words such as 'interesting' are spelled as 'interestin.' The combination 'is not' is often represented as 'ain't.'

So long as there is intralanguage variation, there will always be one or more speech varieties in every linguistic community that are the targets of dialect humor. It is also likely that negative stereotypes exist of the speakers of such varieties and that they are likely to be perceived as backward, slow-witted or even stupid. Hence those who engage in dialect humor will almost always feel superior to their targets.

Ethnicity and the Crossing of Boundaries
B. Rampton

Sociolinguistics has long been interested in the relationship between language and ethnicity, but it has tended to assume that speakers are relatively settled in their own ethnic identities. More recently, however, research has started to document a range of ways in which people use different speech varieties to renegotiate their ethnic affiliations, and this presents something of a challenge to the traditional sociolinguistic view of language and community.

1. Language and Stable Ethnicities

Two views of ethnicity have hitherto been dominant in sociolinguistics. In the first perspective, ethnicity is seen as a tacit cultural and communicative inheritance, acquired through interaction in the early years at home and in local community networks. Socialization within different ethnic groups is held to produce distinctive patterns of language use, and since the 1960s, sociolinguistics has sought to document these differences, together with the ways in which mainstream institutions in general, and schools in particular, neglect or misinterpret the distinctive linguistic resources introduced by ethnically diverse populations (e.g., Labov 1969, Philips 1972). Even so, the idea of ethnicity as an ingrained disposition

faces a serious problem. It is certainly true that deep-seated language habits often make it hard for people to adapt to the standard language practices demanded in modernist institutions, but what are the reasons for assuming that these differences are best understood as being rooted in ethnicity rather than, say, class, gender, neighborhood, family etc? The language practices in question seldom exist in perfect overlap with ethnic category membership, and so on its own, independent of a host of other social variables, ethnicity is inadequate as a basis for understanding the origins and distribution of these differences.

The second perspective on ethnicity overcomes this problem by emphasizing the interpretations that people make in the situations and moments when particular forms are actually being used (and discussed). Rather than being a symbolic meaning inscribed in the linguistic objects there-and-then during the period when they were first acquired, 'ethnicity' is seen as one of the discursive and cultural frameworks that participants use to make sense of distinctive language practices in the here-and-now. In this view, language use is 'ethnic' where participants construe it as such, and it entails the symbolic

assertion (or attribution) of an inherited identity, strategically activated in different ways in different settings. Social backgrounds certainly do endow people with distinctive communicative styles, but rather than being this linguistic and cultural inheritance itself, ethnicity is viewed as a contrastive construct or image, which people use to notice, create, express, and interpret a variety of social and political differences, tensions and solidarities (e.g., McDermott and Gospodinoff 1979, Gumperz 1982). Indeed, seen as a framework that is used to make sense of intergroup relationships, ethnicity is not only an identity that people claim for themselves—it also figures in the identification and description of outgroups, and there are significant bodies of research which show how language is used in the characterization of foreigners (Ferguson 1975), how ethnic stereotypes are linked to language attitudes (e.g., Ryan and Giles 1982), and how racist representations are managed in talk and media discourse (Wetherell and Potter 1992, Blommaert and Verschueren 1998).

These two views of ethnicity have underpinned major research contributions to our understanding of the relationships between language and interaction on the one hand, and culture, ideology and politics on the other. Much of this research has assumed, however, that for the individual, ethnic identity is relatively fixed (though Le Page and Tabouret-Keller 1985 are an important exception). This is obvious in the essentialism of the first perspective, where ethnicity equates with where you were born and grew up, but even in the second, the possibilities for individuals look limited. Where research focuses on ingroup identity, ethnicity has been cast as something that people can only 'turn up' or 'down,' so to speak, either embracing and cultivating the ethnolinguistic legacy passed on by older generations, or alternatively, dropping it as a category that is personally relevant to them. Similarly, in the research on racist representations and outgroup stereotypes, it is generally assumed that speakers know which ingroup they belong to, and that the ethnic categories they are referring to are definitely 'other.'

What happens, though, in situations of intensive interethnic contact, where communities of interest often cut across the boundaries of ethnic descent (so that in the 1991 UK census, for example, 40 percent of Black-Caribbean men aged 16–34 and 20 percent of Black-Caribbean women aged 16–34 were living with a white partner (Berrington 1996: 199)? Equally, what happens when ethnicity is commodified, and ethnic forms, products, and symbols are marketized and widely disseminated as desirable commodities, lifestyle options and aesthetic objects? Both conditions can make people reluctant to confine themselves only to those ethnic identities that (hitherto) dominant ideologies have placed them in, and recent research makes it very clear that 'language maintenance' and/or the 'linguistic assimilation' of minorities are not the only significant ethnolinguistic processes involved in contemporary urban settings. People with majority ethnic backgrounds sometimes shift towards minority ethnicities, and minority languages can play an important role in this process.

2. Ethnicity and 'Language Crossing'

The use of minority ethnic languages by members of ethnic outgroups (both majority and other minority) has now been quite widely documented, and recent studies investigate, for example, the use in the UK of Caribbean Creole by young Anglos and Asians and of Panjabi by Anglos and African Caribbeans (Hewitt 1986, Rampton 1995), the use of Turkish by young people from Iran, Bosnia or Afghanistan in Germany (Auer and Dirim in press), the use of African American Vernacular English by white adolescents in the US (Bucholtz 1999, Cutler 1999), as well as white uses of Spanish in American popular media (Hill 1999). There is considerable diversity in these practices, but racism and social stratification are often powerful circumambient influences, and these can make 'language crossing' (as this process has been called) a sensitive and ambiguous practice.

Whenever speakers make clear but unexpected use of a speech variety that is not normally associated with them, they are likely to draw attention and/or commentary from their audience, and if there is a sense that they are moving across ethnic boundaries that are sharply felt, the legitimacy of their action may well be challenged. In line with this, crossing often occurs in moments and events where the routine flow of everyday social order is uncertain or relaxed, and switches into a conspicuously outgroup language can be found in activities and genres like greetings, self-talk, jocular abuse, games and musical performance—activities and genres where other people are less likely to think that the speaker truly believes in the identity he or she is projecting. Even so, crossing is a practice that is open to very different kinds of meaning and interpretation. In some occurrences, crossing is fairly obviously intended as parodic mockery and derogation, though the racist force of this is often partially masked in humor. Elsewhere, with crossing into an ethnic variety that has popular cultural prestige and is associated with urban 'cool,' there is a risk of looking pretentious, or being accused of expropriating a valuable resource that rightfully belongs to other people. There are other circumstances, however, where shared experience, friendship and co-memberships of class, generation, gender, neighborhood, etc. outweigh ethnic difference, creating a space where it is relatively safe to explore or experiment with the ethnically specific linguistic and cultural resources that 'belong' to your interlocutor(s). In fact, here crossing can

play an important symbolic role, as illustrated by British youngsters of Pakistani descent who take their white friends' knowledge of Panjabi words as a sign that they are 'in our sort of community' and 'one of us.' Admittedly, for some, this kind of cross-ethnic engagement belongs to a phase of relatively intensive interethnic sociability that eventually proves ephemeral, but for others, the affiliation can be enduring. In one way or another, though, crossing can play a significant role in 'the construction of...a new conception of ethnicity: a new cultural politics which engages rather than suppresses *difference* and which depends, in part, on the cultural construction of new ethnic identities' (Hall 1988: 29 original emphasis).

3. 'Language Crossing' in Sociolinguistics

The language practices sketched above can be socially consequential, and defining it as the use of a language variety that somehow feels anomalously 'other' and that is not readily acknowledged as an uncontroversial part of the speaker's habitual repertoire, 'language crossing' is convenient as a general term to identify them. But how does 'crossing' as a concept relate to sociolinguistics more generally?

Although 'crossing' can play a significant role in the enunciation of new ethnicities, other linguistic processes are obviously also involved. Minority ethnic language forms often become integrated into multiethnic local vernaculars in more routine ways, and if 'crossing' was emphasized to the exclusion of these less noticeable developments, it would run the risk of reifying interethnic processes, implying a movement from one well-defined ethnic category to another when in fact these categories were changing, blurring and/or merging. Indeed, even when speakers in ethnicity-salient situations switch fairly conspicuously into a variety outside their normal repertoire, the boundaries they are crossing are not necessarily interethnic—the voice or language they are putting on can, for example, be some relic from an ingroup inheritance that is attributed to them but that generally, they are keen to leave behind, as when people with family links to another country do versions of the 'foreigner' varieties either spoken by the generation that migrated, or as caricatured in dominant media. In sum, the 'others' evoked by this kind of code-switching can exist in a range of complex and intimate relationships with the speaker's habitual self, and these other voices and personae can also be related to, for example, generation, gender, region, even specific individuals (Hall 1995, Johnstone 1999). In fact, along with all these other kinds of symbolic evocation, the crossing practices described in Section 2 can be usefully subsumed within Mikhail Bakhtin's (see *Bakhtin, Mikhail M.*) much

more encompassing notions of stylization and 'double-voicing' (Bakhtin 1984, Rampton 1999).

Even so, as a contemporary illustration of Bakhtinian processes in operation, research on ethnic language crossing presents a particularly vivid challenge to two assumptions that have been fundamental to sociolinguistics, at least in the 1970s and 1980s: (a) the idea that language study is centrally concerned with systematicness in grammar and coherence in discourse, and (b) the belief that these properties come from community membership, that people learn to talk grammatically and coherently from extensive early experience of living in fairly stable local social networks (Pratt 1987). Sociolinguists certainly have fought hard against the view that language and society were homogenous and they have championed ethnolinguistic heterogeneity, but on encountering diversity and variation, their strongest instinct has been to dig out what they imagine to be the orderliness and uniformity beneath the surface, an orderliness laid down during early socialization. In contrast, language crossing presents us with a salient and sometimes socially productive interactional practice that contests preconceived ideas about family rootedness, and it also often makes extensive use of (non-family) material from public and popular media. In crossing, ethnolinguistic resources are drawn into the spotlight for reflexive evaluation and critique among the participants (Bauman and Briggs 1990, Kroskrity et al. 1992), and the central role it gives to improvization, rupture and the denaturalization of convention makes structural regularity and tacit systematicness in language highly problematic as governing research preoccupations.

At another level, research on crossing draws sociolinguistics alongside relatively recent developments in the humanities and social sciences, where instead of trying to define the core features of any social group or institution, there is major interest in fragmentation, hybridity, indeterminacy and ambivalence, in boundaries of inclusion and exclusion, and in the flows of people, knowledge, texts, images, and objects across social and geographical space. There is a widespread feeling in sociology, for example, that the image of society as a 'compact, sealed [and systematic] totality' is rather uncomfortably based on an idealization of the nation state (Bauman 1992: 57), and that 'the reality to be modelled is...much more fluid, heterogeneous and "under-patterned" than anything that sociologists tried to grasp intellectually in the past' (Bauman 1992: 65). Racism and ethnicity continue to be powerful forces in both politics and history, but sociolinguistics needs to ensure that essentialist assumptions about language and community do not inadvertently obstruct our efforts to understand these processes. The study of ethnic language crossing can help us to avoid this.

Ethnicity and Language

E. F. Kotzé

The relation between language and ethnicity can best be understood within an ecological framework, i.e., as an interactional relation between the societal environment and the speakers of a language (or language variety) who are structurally integrated into this environment (Haugen 1972: 325). This means that the relation between language and ethnicity is an indirect one, only observable through the ways in which speakers use language to signal ethnic identity. Like many frequently used terms, 'ethnicity' has several connotations, some of which are stigmatized (see Sect.4) and some not. This article will deal with both types in order to reflect as closely as possible the full spectrum of interpretations. Likewise, the meaning of the term 'language' can vary considerably, depending on the context. It can, for instance, be used to refer to a particular language, like French, to usage (as in 'Watch your language!'), to literary style (as in 'the language of Shakespeare'), to a particular variety (such as the language of the Gypsies), and so forth. Because ethnicity is primarily concerned with group identity, in this article 'language' refers to either the comprehensive label attached to all the varieties subsumed under a language name, such as English, or to a single variety, which will be specified with reference to the group of speakers associated with that variety (e.g., African American Vernacular English).

Most authors do not distinguish between ethnicity and ethnic identity (cf. Hoffmann 1991: 194), and Edward's definition (1979: 10) of ethnic identity thus equally applies to ethnicity:

> Ethnic identity is allegiance to a group—large or small, socially dominant or subordinate—with which one has

ancestral links. There is no necessity for a continuation, over generations, of the same socialization or cultural patterns, but some sense of a group boundary must persist. This can be sustained by shared objective characteristics (language, religion, etc.) or by more subjective contributions to the sense of 'groupness,' or by some combination of both.

An objective characteristic which Edwards introduces later, namely race (Edwards 1979: 254), has contributed a great deal to the controversy surrounding the use of the term 'ethnic,' and whenever it is implied as a factor in determining ethnicity, a racialist bias is assumed (see also Sect. 4).

Ethnic communities are similarly defined by reference to both subjective and objective aspects. Smith (1982: 147) proposes a definition of an ethnic community as

... a group of people who possess a myth of common ancestry, a shared history, one or more elements of common culture and a sense of solidarity.

In the wider context of society, ethnic groups interact because of environmental factors influencing their members. This is a corollary of the ecological approach to the study of language and ethnicity. In this framework, external and internal ecological factors can bring about integration or separation of ethnic groups. For instance, the isolation of such a group may be due to the fact that it is geographically separated from other groups. This is an external ecological factor. On the other hand, the members of a group may be averse to contact with another group, in which case the isolation is an internal ecological factor (Haarman 1986: 1). Because interethnic relations are primarily conducted by means of language, a thorough understanding of the function and place of ethnicity in society cannot be achieved if the linguistic effects (and causes) of such interaction are ignored.

1. Language as Marker of Ethnicity

Language is not only used as a tool for communication and individual expression—the use of a particular language or language variety often serves as an indication of the speaker's group identity. Furthermore, the way in which such a language is used, through pronunciation, syntactic construction and the inclusion of vocabulary items, is not only indicative of the speaker's membership of an ethnic group, but expresses relevant cultural items (types of clothing, aspects of wedding rituals, etc.), and it is often thought that such cultural lexical items are untranslatable (Fishman 1977: 25).

1.1 The Role of Ethnicity in Mother Tongue Varieties

Although ethnicity is often linked to national identity (see Sect.3.2), and language can be regarded as the most central symbol of emerging nationhood, poli-

tical entities that comprise a homogeneous, monolingual national group are rare (Crystal 1987: 34). In fact, a study by Connor revealed that only 9.09 percent of all existing states in 1971 were true nation-states, in that for all practical purposes only one ethnic group constituted the total population. The multiplicity of language groups in multilingual states (which often correlate with ethnic groups) is further complicated by the fact that various ethnic groups may share the 'same' mother tongue, albeit different varieties, or ethnolects, of that language. A case in point is the variety of English in the USA now known as 'African American Vernacular English' (AAVE), which is spoken by lower-class African-Americans in urban communities. In spite of the existence of strong emotions regarding the sociolinguistic classification of this variety and the color prejudice which has promoted the (linguistically invalid) view that 'black' English is necessarily inferior to 'white' English, AAVE and standard American English are both widely regarded as the same language, and its speakers as having the same mother tongue. However, there was a strong counter-argument central to the Ebonics controversy of the 1990s (see *Ebonics and African American Vernacular English*) that AAVE was structurally, historically, and culturally independent of the mainstream. A comparable situation is that of the language spoken by the Cape Muslim, or Malay community of Cape Town, whose variety of Afrikaans is characterized by a large component of Islamic vocabulary (Arabic or Malay loanwords), as well as a rapidly expanding percentage of English loanwords, a fully deflected auxiliary verb system and advanced phonological assimilation.

In some cases, notably among Native Americans, ethnic sentiment is reinforced when individuals give up by force of circumstances their own minority ethnic language in favor of a common (English) lingua franca, which may itself become a new marker of ethnicity (Ross 1979). A comparable change in ethnic association occurs among West Indians in the UK (documented by LePage and Tabouret-Keller 1982), where, because of the attitudes of white Britons, island labels and island identities were replaced by a general West Indian (British) identity. These examples illustrate the fact that ethnic identity is not dependent on language loyalty to the ancestral mother tongue. The subjective forces of a sense of solidarity here and now can surpass the objective reality of a shared history and a myth of common ancestry in which a particular language served as a symbol of identity.

1.2 Ethnicity in Cross-cultural Communication

On the interface between culture, ethnicity, and language lies the ritualization of communication patterns. Pragmatic rules exist in every ethnic group which determine the sequencing of questions and

replies in starting a conversation. Among the Nguni and Sotho in Southern Africa, for instance, an interlocutor is obliged to enquire about his addressee's well-being before coming to the point. In an exchange of greetings, it is expected that a socially superior (older) person will speak first. In some Western cultures, however, a socially subordinate (or younger) person is required to show respect by greeting first. It is clear that bilinguals (or monolinguals being addressed in their mother tongue by a bilingual person from another culture) who are not informed about the pragmatic rules governing successful communication in the 'other' culture could unintentionally cause misunderstanding, which might in turn lead to negative stereotyping and even conflict.

Sociocultural relations (such as family structure and status differences) are often reflected in the lexicon of particular ethnic groups. Terms of address vary according to the particular setting, age difference, and relative social position of asymmetric dyads (or peers) involved in conversation. A number of researchers, starting with Brown and Gilman (1960), have studied address systems in different cultures, based on the choice between the formal and informal second person pronouns and verbs (cf. French *tu parles*, German *du sprichst*, informal mode, with French *vous parlez*, German *Sie sprechen*, formal mode) in a number of European languages, to express a relation of power or solidarity with the addressee. Here again, if a bilingual speaker, when addressing native users of another language, applies the same set of pragmatic rules governing address forms in her/his mother tongue, (s)he may appear to be rude, arrogant, strange, or ignorant, because (s)he does not observe the concordance of linguistic items and cultural conventions.

1.3 The Role of Ethnic Attitudes in Language Maintenance

Although it has been shown (see Sect.1.1) that the use of a particular language need not be an integral part of ethnic identity, it can be indicated that where language does have such a symbolic value, there is a very close link between a person's identification with an ethnic group and the (continued) use by that person of the language which is a component of the group's ethnic identity. The language preference of a group of bilingual Gujarati- and English-speaking students in Leicester, UK was studied by Mercer et al. (1979), who found that the degree of identification with being Indian rather than British correlated positively with the use and maintenance of Gujarati. In another study (Lowley et al. 1983), representatives of three American ethnolinguistic groups, French, Spanish, and Yiddish, were interviewed, and the conclusion was that all three groups wished to maintain their specific ethnic identity alongside their

American identity. Their ethnic mother tongue was considered to be its most vital and visible expression (see Appel and Muysken 1990: 14).

It is also possible that language shift can take place, i.e., that a group can lose its original language and, for whatever reason, adopt another one, but that the 'lost' language still retains a particular symbolic value for the group, thus contributing to the maintenance of ethnic boundaries (cf. Irish Gaelic in the Republic of Ireland). This situation obtains especially among immigrant communities who have been assimilated linguistically into their adopted country, but retain their ancestral language for religious or cultural purposes (eg., Hebrew among American Jews; Tamil, Hindi, Urdu, Gujarati and Telugu among South African Indians, etc.).

2. Ethnicity in Language (and Human) Rights

The subject of the constitutional accommodation of the language rights of ethnic minorities is often a bone of contention. Whereas human rights are based on the freedom of the individual, language rights involve, of necessity, the prerogative of ethnic groups to use their mother tongue in multilingual situations, something which has the potential of causing conflict. Such conflict can only be resolved by means of language planning, and more specifically status planning. The title of a book by Tollefson (1991) touches on the essence of the problem: *Planning Language, Planning Inequality*. In an unpublished manuscript, Neustupny (reported in Bartsch 1987: 241) says: 'It is obvious that any act of language planning seriously affects language rights of the community concerned.' If a particular language is either selected as official language, or otherwise chosen as a medium of instruction by a majority of speakers in the community, members of an ethnic minority with a different mother tongue have to acquire a sufficient command of the chosen medium to be able to benefit from the education system. Individual levels of proficiency will further determine the degree of academic (and possibly professional) success of such speakers. The inference is that the functions of ethnic minority languages can be severely curtailed, be it through legislation or convention, to the disadvantage of individual members of the group.

3. The Resolution of Ethnolinguistic Problems

Problems resulting from the interaction of ethnic groups in a multilingual environment can range from minor to severe, depending on (a) the importance of the mother tongue for the specific group, and (b) the degree to which restrictions are imposed upon members of the group because of their dependence on the mother tongue for self-fulfillment. The resolution of such problems is to be found either in

the field of politics (where the granting of language rights is determined) or in the field of education (where the status quo is accepted and addressed, and an attempt is made to facilitate the process of acculturation).

3.1 Problems in the Field of Education

The phenomenon of ethnic groups (minority or majority) who are dependent on the use of another language for their educational needs is a worldwide one, and occurs in practically every country in Africa, where the erstwhile colonial languages have continued to serve as medium of instruction. It is not to be denied that this situation can cause enormous problems. Skutnabb-Kangas (1984), for instance, attests that unless the educational system takes proper account of minority (read also 'majority,' in the African context) children's special language needs in both languages, they will not become fully functional in either of the codes (see *Semilingualism*). Unfortunately, this viewpoint has not been followed generally by educational authorities in either Africa or Western Europe, where the system reflects the one-state one-language principle (see *Multilingual States*) applied for a long time in many countries (Hoffmann 1991: 43). No provision is made for the special linguistic needs of pupils whose home language differs from the medium of instruction. Indeed, repressive methods have been employed in places such as Gaelic-speaking Scotland, Wales, Brittany, Catalonia, and Galicia (in northwest Spain), so that children were forced to acquire the language of the majority under difficult circumstances (see *Linguicide*). In some countries, however, there exists nowadays a more lenient approach to the plight of ethnic minorities at school. Special classes have been instituted to assist children in learning the second language before they are assimilated into the educational mainstream (e.g., English as a Second Language (ESL) provision, in the UK, and '*Deutsch als Zweitsprache*' for migrants' children in some German states). Voluntary private schemes to teach minority-language children who already form part of the mainstream system are also in evidence in France, the UK, Germany, and Scandinavian countries, but their success is dependent on individual participation, motivation, and resources.

An approach which is widely followed in Africa is to select as the medium of instruction a language which is ethnically neutral (invariably also an official language) because of the fear of 'tribal dominance' (Schmied 1991: 27). In most cases, the former colonial language was an automatic choice: it served as a symbol of erudition and provided access to well-developed resources. However, in the case of Namibia, a politically motivated preference was exercised against the selection of Afrikaans (which had been the colonial language), because a large percentage of citizens use it as mother tongue, and the continued use of the language as the medium of instruction would have benefited that group (cf. Schmied's reference to fear of 'tribal dominance' above). The solution is then what can be termed the 'equal distribution of disadvantage,' in that English, the selected medium of instruction is a second (or foreign) language to the vast majority of inhabitants, and all ethnic groups are therefore on an equal footing with regard to the task of having to master another language in order to benefit from the teaching.

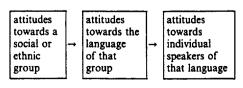
3.2 Problems of Language Politics as a Result of Ethnic Attitudes

Because a language very often is linked to the identity of an ethnic or social group, this relation finds its expression in the attitudes of the individuals towards such a language and its speakers. Appel and Muysken's (1990: 16) illustration of the resulting chain reaction is shown in Fig. 1. Negative attitudes towards a particular language and its speakers mostly originate in the fear that the target group, and therefore its speakers and its language would pose a threat to the continued well-being of one's own group, its culture, and language. When there is enough solidarity among the threatened group, collective action and insistence on the accommodation of language rights for that group might follow. Many examples of such actions have been recorded, among others the campaign for French in Quebec, Canada, for Flemish in Belgium, for Welsh in Wales, and for Catalan in Catalonia, Spain. An ethnic majority in a particular region speaking the language as mother tongue can achieve some success in this respect, as it is evident from the position in the early 1990s of Catalan, which was used on an equal footing with Spanish at the 1992 Olympic Games in Barcelona. In Wales, however, less than five percent of the population speak Welsh, and the basis for wider recognition of the language is weakened by this fact.

Language as a symbol of ethnicity may contribute also to shape and maintain feelings of national identity and solidarity. The so-called 'ethnic revival' which is especially apparent in Eastern Europe, has led to secessionist struggles and the creation of new political entities based on cultural (and particularly

attitudes towards a social or ethnic group	→	attitudes towards the language of that group	→	attitudes towards individual speakers of that language

Figure 1.

327


language) identity. Events in the former Yugoslavia and the (peaceful) resolution of the ethnic conflict in Czechoslovakia are indicative of the strong link between language, nationalist sentiments, and ethnicity.

4. Changing Views on Ethnicity

The first connotations given to the terms 'ethnic' and 'ethnicity' reflected a patronizing attitude among British and French lexicographers towards non-European peoples. In the third edition of *Chamber's Twentieth Century Dictionary*, for instance, the noun 'ethnic' is glossed as 'a heathen,' 'ethnicism' as 'heathenism,' and 'ethnography' as 'the scientific description of the races (sic) of the earth.' In *Petit Larousse Illustré* (1973) the lemma 'ethnolinguistique' is defined as the study of the speech of illiterate peoples. The 1990 edition of the *Concise Oxford Dictionary of Current English* provides for a wider variety of possible meanings of 'ethnic' (adj), inter alia '(of a social group) having a common national or cultural tradition,' '(of clothes) resembling those of a non-European exotic people,' 'denoting origin by birth or descent rather than nationality (*ethnic Turks*),' 'relating to race or culture (*ethnic group*; *ethnic origins*),' '(archaic) pagan, heathen.' The expression 'ethnic minority' is defined as 'a (usu. identifiable) group differentiated from the main population of a community by racial origin or cultural background.' In scientific literature, especially in linguistics (including socio- and ethnolinguistics), the reference to racial origin has become irrelevant, because of the much finer distinctions required when comparing groups on a worldwide scale. However, in countries where ethnicity and color are burning political issues (e.g., South Africa and the USA), the terms 'ethnicity' and 'ethnic' have come to be regarded as synonymous with 'race' and 'racial' in common parlance, and thus are treated with some suspicion.

However, the phenomenon of ethnicity itself is being reevaluated because of the collapse of socialism in Eastern Europe and the realization that individual and group rights can be attained in a more democratic environment. This is leading to a reawakening also of interest in ethnic minority languages and identification with the languages of the group as a symbol of group identity.

5. Ethnicity: Cause or Result of Language Change?

There can be no doubt that the adoption of a language other than the ancestral one by an ethnic group will lead to the genesis of a new variety of the adopted language (see Sect. 1.1). This variety will be influenced, not only by structural elements of transfer from the ethnic group's original mother tongue, such as pronunciation and syntax, but indeed also by lexical items expressing ethnic characteristics of the group. Reference has already been made to such characteristics in Malay Afrikaans, but immigrant varieties of English in the USA, such as the Italian and Yiddish ethnolects, contain typical items of vocabulary from the relevant cultures, in addition to elements of language transfer. Such influence is known as a substratum effect (see *Language Transfer and Substrates*). However, the development of such a new ethnic variety need not always be in the direction of the substratum language. Sometimes immigrants attempt to overcorrect what they feel to be a faulty accent, resulting in a change away from the substratum language, to such an extent that their variety of the adopted language develops new characteristics (Aitchison 1984: 117). Labov has indicated, for instance, that second-generation Italian–Americans, instead of using the native Italian low vowel [a], as their parents do, in words such as *cap, fat, tack*, tend to raise the vowel to [e] as a corrective for the influence of Italian (Labov 1978: 298). This form of 'hypercorrection' is a typical characteristic of ethnic minorities reacting to the environment of a different culture.

As language is one of many indices of ethnic identity (and not even an essential one), the effect of language change cannot have a determining effect on the underlying ethnicity of a group. So, even if a group adopts a new language, the basic patterns of ethnic behavior remain undisturbed by it, and can only be altered by a more encompassing process of acculturation.

6. Conclusion

After considering the different ways in which language and ethnicity interrelate, it can be concluded that there exists no necessary relation between ethnicity and a particular language. In his study of the language of ethnic groups in Canada, Lieberson (1970) noted that there are many instances of such groups with distinct languages, but also groups sharing a common language. A particular language, therefore, may or may not be included in the group's cultural bag (Appel and Muysken 1990: 15). However, it is also evident that the language, or variety of a shared language used by an ethnic group, becomes characterized by elements of that group's ethnic identity and reflects the interaction between man and its cultural environment in a very distinct way.

Forensic Phonetics and Sociolinguistics

P. Foulkes and J. P. French

Forensic analysis of speech and language is a relatively young discipline. A specialist academic and professional journal for the field—*Forensic Linguistics: the International Journal of Speech, Language and the Law*—was only established as recently as 1994. Appropriate strategies for applying phonetic and sociolinguistic knowledge and methodologies to legal problems are in the process of being refined, expanded, and their reliability tested.

The International Association for Forensic Phonetics (IAFP) was established in 1991 in order to regulate and assist the practice of speech analysis for legal purposes. It aims to ensure practitioners are suitably qualified, to fix ethical and practical guidelines for analysis, and to promote research in the area (see www.iafp.net). Another important role played by the IAFP is to raise awareness among members of the legal profession and other interested parties of both the values and also the limitations of forensic phonetic analysis.

Applications in the legal context of techniques developed in phonetics and sociolinguisticsfall into four main categories: (a) deciphering the content of 'difficult' recordings; (b) speaker profiling; (c) speaker identification; and (d) constructing voice 'line-ups' in order to evaluate ear-witness testimony. These activities are discussed in turn below. More extensive introductions can be found in French (1994), Hollien (1990), Künzel (1987) and Nolan (1991, 1997).

1. Deciphering the Content of Difficult Recordings

Tape recordings, which may contain information relevant to court hearings, can be problematic or difficult to decipher for a variety of reasons. For instance, they may be contaminated by extraneous noise, which obscures the conversation of interest, or the speakers may have pathological or otherwise nonstandard—perhaps foreign—patterns of pronunciation.

In relation to noisy recordings, the sound filtering and signal processing techniques developed by audio engineers can be of help in improving speech to noise ratios and thereby rendering the speech signal more

329

audible/intelligible. However, phonetic and socio-linguistic analysis may also be crucial in arriving at a final determination of what was said.

Hirson and Howard (1994), for example, analyzed the content of the 'black box' flight recorder recovered from the wreck of a South African Airways aircraft which had been lost in mid-flight in 1987, with the loss of 159 lives. The black box records the last 30 minutes of activity in the aircraft's cockpit, via a microphone housed in the ceiling. It was hoped that the spoken material would offer vital clues as to the cause of the accident. However, the recording proved to be problematic in various respects: the tape was highly degraded after having spent over a year under water; it contained only 81 seconds of speech after the first indication that there was a serious problem (a fire alarm); and the aircraft crew were multilingual, speaking English and Afrikaans. The poor signal-to-noise ratio of the recording meant that even deciphering which language was being spoken was far from straightforward. Ultimately, phonetic (auditory and acoustic) analysis enabled the majority of the spoken material to be transcribed, and revealed no evidence of a bomb, or of human error on the part of any of the crew. This case also resulted in recommendations to the Federal Aviation Administration for improving the structure and positioning of flight recorders.

In certain instances the problem of interpreting the content of a recording may be extremely 'localized,' with only a closely circumscribed section of speech being at issue. Such cases have been referred to as ones involving 'disputed utterances' (French 1990). The latter study reports a case concerning a Greek-born doctor working in the UK, who had been accused of illegally prescribing drugs for profit. An investigative journalist, posing as an addict, managed to obtain a prescription for a controlled drug and secretly recorded the encounter. The dispute, at a subsequent Medical Council tribunal, concerned whether the doctor had told the journalist 'you *can* inject those things,' or whether he had warned 'you *can't* inject those things.' The disputed word was pronounced [kan]. While such a pronunciation would clearly indicate *can* in Standard British English, it is ambiguous in other varieties, including the Greek-accented one spoken by the doctor. In order to assess which word was intended, acoustic analysis was undertaken to compare the disputed word with undisputed examples of *can* and *can't* from the doctor's speech. Although they were auditorily very similar, analysis of the vowel formant frequencies revealed that the disputed word more closely matched the doctor's formant patterns for *can't*.

2. Speaker Profiling

A combination of phonetic and sociolinguistic analysis of a voice can aid in establishing information about the speaker's background. Speaker profiling is regularly requested in the early stages of kidnappings, where a recording of the kidnapper's voice may be the only clue to his or her identity. Information can be gleaned about the speaker's sex, age, regional and social background, and idiosyncrasies such as speech disorders. The strength of conclusions varies and is highly dependent on the length and quality of material, the degree of any disguise involved, and the extent of descriptive dialectological and sociolinguistic information available. Establishing a speaker profile helps in defining a 'target' population and thereby narrowing the search for the culprit.

One of the best known examples of speaker profiling was undertaken in the case of the serial murderer known as the 'Yorkshire Ripper' (Ellis 1994). During the investigation the police received tapes from a man claiming to be the killer. Profiling by Ellis established that the man most likely came from, or had lived for a substantial period of time in, the Sunderland area of northeastern England. However, time proved that the real killer in fact came from Yorkshire, a county to the South of the area identified. The sender of the tapes, who was evidently a hoaxer, remains at large.

Detailed phonetic analysis may also serve to indicate the likelihood that a speaker is intoxicated, although the precise effects of alcohol on speech are not clearly understood or consistent across individuals (Künzel et al. 1992). The recorded speech of the captain of the Exxon Valdez oil tanker, which ran aground in Alaska in 1989, was investigated to assess whether he was intoxicated at the time of the accident (Hollien 1993).

More recently, sociophonetic analysis has been used as evidence to pinpoint the origins of asylum seekers in some European countries, in order to verify the legitimacy of their asylum claims (Simo Bobda et al. 1999).

3. Speaker Identification (SID)

Perhaps somewhere between 70 percent and 80 percent of all forensic cases involve SID: that is, identifying, by means of comparative phonetic testing, a person heard speaking in a criminal recording. A 'criminal recording' in this context may be anything from a hoax bomb warning recorded over an emergency telephone line, to a death threat left on a tape posted through the victim's letterbox, or a surveillance recording made secretly by the police within the home of someone planning a robbery.

The commonest scenario is for a forensic phonetician to compare the questioned voice in the criminal recording with a speech sample from the suspect, in order to assess the likelihood of their being the same person. Labov (1988), for example, reports the case

330

of a New Yorker accused of making threatening calls to Pan Am airlines. Detailed phonetic transcripts and instrumental evidence comparing the caller with the accused suggested beyond reasonable doubt that the caller was in fact from Boston, resulting in the acquittal of the accused. Many other example cases are detailed by Baldwin and French (1990), and in the journal *Forensic Linguistics*.

It is now widely accepted that there is no indelible feature of an individual's voice. That is, there is no vocal equivalent of a fingerprint or a DNA profile, which can offer irrefutable proof of speaker identity. Research in sociolinguistics and phonetics has shown that an individual's speech may vary as a result of many factors, including the dimensions of the vocal tract, and features acquired as a result of the speaker's social and regional background. Speech features may also vary markedly from situation to situation: for example, as a result of stress, conscious disguise, or the effect of speaking on a telephone. Different voices may also be affected in different ways. For instance, most people, but not all, speak more loudly when using a telephone, which results in a rise in average fundamental frequency (Hirson et al. 1994).

In casework, various segmental and suprasegmental features may be analyzed, as well as lexis and grammar. Nowadays SID usually includes both auditory and acoustic phonetic analysis, although debate on the relative merits of the two approaches can be found in the earlier literature (Kersta 1962, Baldwin and French 1990, Nolan 1990, French 1994). Much research focuses on determining which phonetic parameters of a voice are the most useful in identifying an individual speaker, and also the degree of variability individuals display along various phonetic and sociolinguistic dimensions. In all cases the strength of conclusion that can be drawn is dependent on reference information, including—where available—population statistics, from fields such as phonetics, phonology, dialectology, sociolinguistics, and speech pathology. For the majority of forensic phoneticians, and all IAFP members, the outcome of an SID analysis is an expression of opinion ranged on a scale of confidence, rather than a categorical statement that the suspect is or is not the culprit. And although either the prosecution or the defence initially engages an analyst, the IAFP promotes the view that a neutral comparison of samples should always be undertaken. Analysts therefore do not set out to try and win the case for the side which engages them.

4. Speaker Identification by Lay Witnesses

While the bulk of forensic cases involve speaker identification by linguists using tape-recorded materials, in certain cases there is no permanent record of the voice involved in the crime. Instead, the perpetrator may simply have been heard by a 'lay' (i.e., phonetically-naïve) witness. Examples include the receipt of obscene phone calls, or witnessing a crime committed in the dark or by a masked robber.

It is now generally acknowledged that a witness must be able to demonstrate recall of a voice in a formal test, although this has not always been the case. Milroy (1984) reports a blackmail case from Northern Ireland in which a family received telephone threats following an incident where a masked intruder had entered their home. A suspect was arrested and subsequently given a ten-year prison sentence after his voice was overheard in a police station by the family members. No formal testing established their ability to identify the suspect as the man who had made the phone calls. Milroy's analysis of the sociolinguistic features of the suspect and the phone caller later revealed significant accent differences between them.

The most likely means of testing a witness's recall of a voice is by identifying the perpetrator of the crime in a *voice parade* or *line-up*. This consists of a set of recorded voices, including that of the suspect. In such cases forensic phoneticians may be called upon either to construct the parade itself, or to analyze the contents of the parade to ensure that no samples stand out unfairly in relation to the others, for example through a markedly different accent, voice quality, or recording fidelity. A detailed description of the construction of a voice parade for use in a rape case is provided by Nolan and Grabe (1996), while Butcher (1996) exemplifies the assessment of samples in a voice parade used to identify an armed robber.

There is at present, however, no incontrovertible method of constructing or administering a voice parade (see Broeders 1996, Hollien 1996). However, the most carefully argued and rigorously constructed set of guidelines may be found in the seminal article by Broeders and Rietveld (1995).

Testing recall of voices is complicated by research showing that witnesses' performance in recall tasks varies markedly as a result of numerous factors. These include hearing ability, the degree of familiarity with the voice, and whether exposure to the voice was active or passive (Künzel 1994).

It is widely assumed that recall of familiar voices is straightforward or even automatic. However, while it is generally true that recall of familiar voices is better than that of unfamiliar ones, even close friends and family members can show a significant degree of inaccuracy or inability to recognize voices that are well known to them (Foulkes and Barron 2000). It has also been demonstrated that memory of a voice tends to decay over time, so that it is imperative to begin constructing a line-up test as soon as possible after the witnessing of the event

331

(Hollien 1996). In practice, though, there may be long delays as a result of failure to apprehend a suspect quickly.

5. Conclusion

There remain many controversial issues in the practice of forensic phonetics. As far as speaker identification is concerned, it is unlikely that any speaker-specific invariant parameter will ever be discovered, such that statements of speaker identity might come to emulate the strength of those derived from DNA testing or fingerprinting. That said, it is encouraging that research in relevant areas is undergoing continued growth.

Gay Language

W. L. Leap

Gay language is a relatively new area of interest in sociolinguistics. The recent emergence of this topic reflects, in part: the general growth of lesbian, gay, bisexual, transgender, and queer studies within many academic disciplines; efforts in feminist theory to move beyond binary-based discussions of female/male differences and to examine gender dynamics in historically situated, socially constructed terms; as well as a maturing of the interests in language, gender, and sexuality which have been addressed through sociolinguistic research for some time.

1. Defining Gay Language

The subject matter of gay language research continues to be a matter for discussion. Earlier work assumed somewhat unquestioningly that gay men and lesbians use language in distinctive ways, and called for studies designed to explore the details of this linguistic distinctiveness. The results of these

studies included collections of words relevant to gay or lesbian experience, and descriptions of language use in situations where the gay or lesbian focus of the speech event was already marked, e.g., humorous conversations in gay bars (Goodwin 1989), silence during anonymous sexual encounters (Delph 1978), verbal dueling at all-gay dinner parties (Murray 1979), and linguistic risk-taking in conversations in department stores, airplanes, and other public locations (Leap 1993).

In most cases, these studies take for granted the speakers' lesbian, gay or other same-sex identities, and leave unexplored how text-making contributes to and frequently confirms the speakers' understandings of sexual sameness. What results is a seemingly circular relationship between language and identity, where use of gay language is confirmed by the (homo)sexuality of the speaker, while at the same time speaker sexuality is confirmed by those self-same linguistic practices (Kulick 2000).

Understandably, more recent research has begun to look more closely at these particular relationships which link language use, (homo)sexuality, and speaker subjectivity. Some of these studies examine the linguistic practices through which same-sex identified women and men construct or conceal claims to sexual identity within speech events (Leap 1996: 49–73). Other studies show how a speaker's use of certain linguistic practices prompt interlocutors to *assume* gay/lesbian presence within the speech event, whatever the speaker's claims to sexual identity (Cameron 1977). And others explore how a speaker's use of particular linguistic practices bring messages about sexual sameness into the foreground of an otherwise heterosexually focused text-making, or otherwise transform (or 'queer') the linguistic moment (Gaudio 1997).

These examples remind us that same-sex desires and experiences are constructed within the social moment and must be studied within linguistic and social context. Marginality is also a part of that context, and so are the heterosexism and homophobia which often surround public expressions of same-sex identities, practices and desires. In some ways, these politics are similar to those surrounding linguistic practices of *any* group of speakers located at a distance from domains of power and privilege. Accordingly, there is some interest in broadening the focus on *gay* language study within sociolinguistics to a more inclusive focus on language and desire (Kulick 2000). At the same time, broadening the focus diverts attention from a close analysis of particular linguistic practices and their connections to other features within the social context. Understandably, another emerging line of inquiry proposes exploring connections between language, sexual identity, and same-sex desire within the context-

centered structures of political economy (Leap in press).

2. Characteristic Features, Uniqueness vs. Significance

Whether there are characteristic features of gay language, or whether the 'gayness' of these codes lies outside of textual detail, also remains a matter of ongoing debate. There is some agreement that specialized vocabulary (including words and phrases with unmarked, ingroup meanings), along with phonological features like distinctive intonation patterns and extended vowel length, are some of the features commonly associated with identifiable gay *English* linguistic practice, and some indication that similar features may be attested in other languages. Some researchers would also include in this listing *camping* and *queering* and other forms of trangressive verbal performance, as well as *masquerade, language of the closet,* and other practices of linguistic concealment.

There is less consensus regarding the existence of gay/lesbian-related conversational structures and narrative styles. In some cases, what at first appears to be a specifically gay or lesbian focused language use is found to be a reflection of a gay or lesbian topic under discussion, or the linguistic practices which any speaker might employ under similar circumstances, whatever the sexual identity. But even when the linguistic structures reflect gay-centered topics or have parallels in the language use within other speech settings, gay language speakers are still using language to encode gay/lesbian content, speaker identity, or other same-sex related presence strategically within the social moment. Gay-related linguistic practices do not need to be unique to have a significant effect on text-making—and therefore to be of interest to sociolinguistic description.

3. Language Socialization and Language Diversity

3.1 Gay Language Socialization

While language often appears to be a widely accessible cultural resource, gay-related linguistic practices are not always in the foreground of local communication so identifying sources of information, and gaining access to those sources, figure prominently in the coming out process and in subsequent events in the speaker's gay/lesbian career (Leap 1999). The workings of gay language socialization become an even more complex enterprise for would-be speakers now that gay languages are emerging in parts of the world where same-sex desire has not previously been publicly articulated (see Sect. 5.1).

3.2 Gay Language Diversity

Moreover, not everyone learns the gay language of the speech community in entirely the same ways, and not everyone has access to these resources. These variations in gay language/(homo)sexual socialization anticipate the other forms of diversity that structure language use by gay men and lesbians.

3.2.1 Diversities Based on Gender

Building on claims from French language/gender studies, some theorists argue that because language is closely associated with the everyday experiences of men, including gay-identified men, lesbians, because they are women, will always find gay language to be in some way inaccessible (Irigaray 1985, Penelope 1990). This argument endorses a literal reading of the term *gay language*—that is, *gay men's language*—as the focus for inquiry, since lesbian language is an internally contradictory, if not impossible construction, under these conditions. The absence of terminology for women-identified women, compared to the richness of terms for same-sex identified men, is a widely attested reference pattern outside of North Atlantic domains, and is often cited to show how the contradictions surrounding lesbian language can be resolved through public silence. Whether such silence creates opportunities for women-centered discourses to emerge privately, or is another erasure of lesbian/female voices in another form, has to be examined in site-specific terms (Kendall 1999, Thadani 1999).

3.2.2 Diversities Based on Race, Ethnicity, and Class

Gay language is rarely the exclusive property of the affluent, the comedian, the activist, or the academic. Conversations framed in terms of gay linguistic practices, and lesbian linguistic practices where attested, have been reported in all domains of everyday life and among speakers occupying various social and economic statuses. And even though some speakers may appear to be especially proficient in these ways of speaking, gay language is not the parochial domain of any single individual, but is socially constructed and is closely associated with particular 'communities of practice' (Wong and Zhang in press).

While distributed widely, these practices are never distributed evenly across the social terrain. Much as is often found to be the case in sociolinguistic inquiry, divisions of race and class provide important sites of variation in that regard. In the USA, for example, the Gay Men's English, which is stereotyped in films and other forms of popular culture and is widely attested in urban gay venues and other public locales, is closely associated with *whiteness* and with 'passing for white' by same-sex identified men of African American, Hispanic, and Asian/Pacific Islander backgrounds. Members of these groups have

their own ways of expressing same-sex identities and perspectives within their linguistic text-making. This includes an African American gayspeak whose linguistic details draw heavily on kinship terms, discussions of domestic practices and other African American female-associated centered referencing; the *swardspeak* of the Filipino-American *bakla*; the 'talking *kush*' popular among South Asian gay men; or the distinctive Spanish text-making of the Latin American *maricon*.

In the case of swardspeak, the language has strong associations with the Filipino homeland and varieties of swardspeak are attested among same-sex identified men in Manila and in other urban and rural settings. Accordingly, even *gay* identified Filipino-American men, who would never claim *bakla* identity (in public settings, at least) master swardspeak at some level and integrate it into everyday conversations with Filipino same-sex identified friends. That some speakers of swardspeak, whether *bakla* or gay-identified, are also speakers of the white-oriented Gay Men's English is another indication of the complex ties between language, sexuality, and political economy which underlie and help to structure diasporic experience (Manalansan in press).

4. Worldwide Emergence and Globalization

4.1 Worldwide Emergence

Swardspeak is one example of a gay language emerging in one area of the world (the Philippines) and spreading to other areas under conditions of displacement, relocation and other forms of diaspora. Gay languages have equally complex histories in other parts of the world, and are also connected to globalization, diaspora, and other conditions of late modernity in complex ways.

Polari, a gay language spoken by some British gay men during the first half of the twentieth century, had its origins in the antilanguages (see *Antilanguage*) of British criminals, prostitutes, and theater people, and shows influences of Italian and other continental languages, as well. Polari makes use of familiar English vocabulary, but reworks meanings and sentence forms so that speakers can produce statements which are completely unclear to those not familiar with the code (Baker in press). *Gayle*, a gay language spoken in South Africa, also applies coded meanings to a distinct a set of lexical items, many of which are women's names, so that speakers can shield conversations from the surveillance of outsiders (Kleinbooi 1995). Speakers of Polari and Gayle also insist that speaking these languages can be a superb form of recreation.

In North American Indian contexts, traditional gay languages draw more heavily on conventions of sentence structure and meaning found in ordinary discourse. Alterations in such features as pronoun

structures, verb endings and speaker–audience cross-reference markers allow the speakers to code their sexual marginality in formats which audiences will be able to recognize, whether or not they can reproduce them (Thomas 1977).

4.2 Globalizations of North Atlantic-based Lesbian/Gay Languages

'Lesbian' and 'gay' are often used by researchers as markers for same-sex identities worldwide and as indicators of linguistic practices associated with those identities. However, the meanings suggested by 'lesbian' and 'gay' are closely aligned with the emergence of particular forms of same-sex identity under nineteenth and twentieth century North Atlantic capitalism (D'Emilio 1983). As a result, same-sex identified women and men imply connections with North Atlantic-based meanings of same-sex desire when they describe themselves as lesbian or gay or when those labels are applied to them by others. But the circulation of lesbian and gay is not always locally totalizing. With 'lesbian' and 'gay' expressing international meanings, site-specific understandings of same-sex experience are underscored, e.g., by invoking terminology from local languages, by means of paraphrase, by reworking local meanings of 'woman' and 'man,' and/or by silence. Under such arrangements, referring to 'local' languages of same-sex desire as 'gay' language may imply a consistency of same-sex experiences worldwide which is not attested by the historical record or by local life story narratives.

Distinguishing between 'local' and 'North Atlantic'-based languages of same-sex desire is especially important, given that other components of North Atlantic (homo)sexual cultures have joined the transnational flow of lesbian/gay based identity categories and linguistic practices. Primary agents of the circulation include: ever-expanding accessibility of electronic communication; international circulation of films, videos, recorded music, and other popular media; sexual tourism and other travel/tourist practices, voluntary and enforced displacement and diaspora, as well as new understandings of citizenship which sanction *flexible* instead of singular claims to political and cultural identities.

It is a serious misreading of these data to argue that a single 'gay culture'—and with it, a single 'gay language'—is now emerging worldwide. Global circulation of North Atlantic sexual languages and cultures engages local constructions of language, culture, and sexuality in complex ways, sometimes providing helpful alternatives to indigenous understandings and practices, and in other instances prompting an enhancement of details of sexual culture as already locally conceived. The use of English as a language of public lesbian/gay experience in Israel, after years of struggling to adapt modern-day Hebrew for this purpose, is one example of such an outcome (Moriel 1998). The Thai distributions of sexual identities (and with that, associated text-making practices) across English vs. Thai linguistic options is another example: that is, English *gay* is the accepted term for same-sex identified men, while an English based, Thai-like linguistic hybrid *tom dee* (*tom* from the first syllable of *tom-boy*, *dee* from the last syllable of *lady*), provides the marker for same-sex identified females, and traditional Thai reference for male-to-female gender crossing, *cath*, provides the discursive focus for traditional (cross-dressing) as well as modernized (e.g., surgically enhanced) transgendered identification (Jackson and Sullivan 1999).

Gender and Language

K. M. McCormick

As a field of research, language and gender studies is interdisciplinary and relatively new. Until the late 1990s, most sociolinguistic studies of language and gender focused on language as the phenomenon to be explained, and did not recognize the complexity of gender (Cameron 1996).

A wave of intense debate and empirical research was prompted by Robin Lakoff's book *Language and Woman's Place*, published in 1975. This is not, however, to suggest that there was no interest in matters relating to it before that date. Academic papers by linguists, historians, and anthropologists had dealt with some aspects, and written records of various kinds provide evidence that for centuries and in many countries people have had strong beliefs and attitudes about the way women and men speak or should speak, and about acceptable ways of describing males and females. This article describes those beliefs and research into them.

As used here, the term 'gender' does not refer to 'grammatical gender' (the system to be found in some languages of organizing certain word classes into contrasting categories of 'masculine,' 'feminine,' 'neuter'). Here gender refers to social categories based on sex but encompassing behavior, roles, and images that, although not biologically determined, are regarded by a society as appropriate to its male or female members. What is seen as appropriate to each gender thus differs in different societies and eras. Gender is distinguished from 'sex' in that sex is taken to refer to biological characteristics of male and female whereas gender encompasses what is socially learned and acquired. Gender is also distinguished from 'sexuality' and 'sexual orientation' though much research on the latter does not make the distinction clear (see Kulick 2000; *Gay Language*).

Several popularly accepted pronouncements on men, women, and language have been based on the assumption that the different characteristics of male and female language use are a direct result of biological differences between the sexes. Better explanations for almost all observed male/female language differences are to be found less in the biological constitution of the human body and more in the social and psychological formation of the human subject.

A historical perspective on prescriptive and descriptive views of the relationship between language and its male and female users can be gained from an examination of texts written by people with a professional interest in language: lexicographers, grammarians, dialectologists, editors, and, of course, writers of plays and novels. Other sources of information are to be found in a variety of texts produced by people concerned not primarily with language, but with prescribing proper ways of behaving, since one aspect of this is the recognition of the speech community's rules about who may speak and how they may speak in public and private spheres. In most societies these rules indicate differences in what is regarded as appropriate use of language about and by women and men, girls and boys.

In the twentieth century, research in anthropology, sociology, psychology, sociolinguistics, and discourse analysis provided a wealth of interesting material about how various contemporary societies give verbal expression to their perceptions of boys and girls, men and women, about how they regard the language use of their male and female members, and about the factors that impinge upon these attitudes. Some of this work concentrated on describing ways in which aspects of linguistic form vary depending on

sex of speaker or addressee. Other research sought to explain causes and effects of observed covariation and also of patterns in the ways women and men are described.

In the late twentieth century, work on language use was drawn into a broader framework which examined silence and silencing as the other side of the coin of speech and writing. This framework is predicated upon the belief that societal power relationships manifest themselves in the granting or withholding of 'speaking rights' in the broadest sense. In the humanities and social sciences there is an interest in discerning whose voice is heard and taken to be representative or truthful, and whose voice goes unheard in various contexts. A striking example of this is the critical study of colonial history and its rewriting, the narration refocused by the use of different source material. But the privileging of some voices over others does not happen only where two (or more) different societies interact. In all societies some individuals and groups have greater speaking rights than others, especially in the public domain, and the meanings that are encoded in publicly available texts are predominantly those of the society's powerful groups. As men are more powerful than women in most societies, it is their perceptions that are publicly articulated more often than women's and then uncritically taken to be those of the society as a whole. The effect on the socialization of women of this privileging of male perceptions constitutes a focus of research in disciplines such as psychology, sociology, political studies, and critical literary studies (see *Socialization*).

There is a considerable interest in the central role of language in the construction both of the individual subject and of group identity, and as the medium for the expression, maintenance, and questioning of competing ideologies. Of particular note in regard to language and the gendered subject is the work of theorists working in France in semiology, psychology, and philosophy. An understanding of their radical critique of patriarchy and the role of language in sustaining it depends on grasping the ways in which they have engaged with psychoanalytic theory particularly in its Lacanian form. In an article of this length it is not possible to supply the theoretical context that would have to preface an adequate summary of their arguments. For this reason subsequent references to them will provide little more than pointers to some issues on which they focus (see *Identity and Language*; *Ideology*).

Work arising from all of the approaches mentioned above will be touched on in this overview of what is believed, what is known, and what is being investigated about the relationship between language and gender. An examination of gender-distinctive use of linguistic variables will be followed by an account of findings about male and female participation in extended discourse. Socialization processes accounting for male and female differences in language use will be discussed. Finally there is a brief discussion of how gender attitudes are manifested in language as a system. Much of the illustrative material throughout is from Western, industrialized societies because it is there that most research on language and gender has taken place. Where possible, however, perspectives from other societies are included.

1. Gender-distinctive Use of Language

It seems that in all societies gender has a bearing on the distribution of roles and the ascription or achievement of status which then affect access to domains of economic and social activity and to the education that prepares for them (see *Role Theory*). All of these factors, in turn, affect language use. It is therefore not surprising that all societies investigated for the existence of gender-related differences in language use have manifested them. The forms that they take vary from one society to another. They may manifest themselves in preferences for or competence in different languages or dialects; vocabulary; pronunciation; participation in extended discourse(s).

In Koasati, a native American language, a few syntactic structures have different forms for the use of male and female speakers. Less common, but also possible, is that sex of addressee affects choice of form. In Kurukh, a Dravidian language, inflectional morphology is determined by sex of both speaker and addressee. These are two instances of sex determining linguistic form. Rarely is it the only determinant. What usually happens is that it interacts with other factors in shaping what are perceived as gender differences in language use.

Rochefort's seventeenth-century study of a community in the lesser Antilles seemed to indicate that these differences might go as far as male and female members of a speech community speaking different languages. In the community he described the women were Arawaks whose male ancestors had been killed by invading Caribs. The invaders then married the Arawak women. Rochefort claimed that the women preserved their language and taught it to their daughters while their sons, who understood the women's language, preferred to speak the language of their fathers, the result being that the two sexes spoke different languages. However, a re-examination of the data showed this interpretation to be unsound: only 10 percent of the recorded vocabulary on which Rochefort had based his claim was not shared by men and women. In other words, some vocabulary, rather than a whole language, was gender-specific.

There can, however, be differences in degrees of bilingualism between boys and girls, or men and women within a community (see *Bilingualism, Societal*). These tend to be a result of differing educational

337

or economic opportunities for males and females. For example, if the women have to travel to sell wares in a market town while the men are locally employed then the women are more likely to learn a language of wider use than are the men.

Command of the language of wider access may be a factor in a cycle of other changes as was found to be the case in a bilingual community in Austria where Hungarian is associated with peasant life and German with urban opportunities. Moving out of the peasant economy requires, among other things, fluency in German. Those who wish to take this route are using every opportunity to develop their command of this language and it would seem that women feel a greater urgency to do so then men do. Women are choosing to use far more German and less Hungarian than men are. This is prompted by their disinclination to take on the arduous double burden of agricultural and domestic work which is the lot of peasant wives, and by their preference for urban life and work with its labor saving devices and more regular hours. 'Peasant men can't get wives...,' announces the title of an article on language shift in the community (Gal 1978). The outcome of changing marriage patterns will probably be the further withering of Hungarian and a shift toward German (see *Language Maintenance, Shift, and Death*).

The seventeenth-century Antillean community was not unique in having gender-specific lexical pools. Verbal taboo systems can create quite striking differences in the vocabulary available to women and men (see *Taboo Words*). Societies in places as far apart as Mongolia and South Africa have speech communities whose married women are forbidden to use the names of their husband and his male relatives. To use those names would be intolerably disrespectful. The taboo is not limited to the names of male in-laws: it is extended to cover all other words that sound like the taboo names—women have to avoid these and choose synonyms that sound different. For women in these societies, getting married entails a reorientation toward the lexicon of their home language. There are no reports of societies placing comparable restrictions exclusively on men's speech though there is a speech community in Australia which places a taboo on the use of one of its languages by a newly wed couple in the presence of a mother-in-law and some other relatives.

Linguistic taboos of a less far-reaching kind are common. In many societies obscenities are supposedly taboo but in fact it may be acceptable for men but not for women to use them among themselves. In some cases there is an assumption that 'decent women' should not even know these words. That the taboos do not have the effects they are supposed to emerges from empirical studies of men and women swearing. It is not uncommon for there to be covert tolerance of women using obscenities in single-sex

groups, and in some social groups men and women may use them in mixed-sex groups without incurring censure. Age can make a difference as it does in cases where the young women of a community conform to the norms of demureness or silence expected of them, while the older women indulge in raucous and sexually explicit joking.

There is a widespread belief that women's use of language is and should be more refined than men's, while not being expected to match theirs for adventurousness and rigor. The contrasting qualities are often felt to be biologically based, extensions of women's supposedly greater softness and delicacy, and of the greater toughness and energy ascribed to men. To discover whether there is empirical evidence to underpin the belief that women's speech is more refined than men's, the rather subjective notion of 'refinement' has to be tied to observable features of language use—vocabulary, pronunciation, syntax —which the speech community regards as indices (see *Speech Community*).

Vocabulary range in certain fields is sometimes regarded as an index of refinement: for example, a wide vocabulary for color terms and a narrow range of obscenities could be taken to be signs of refinement. There are serious methodological limitations on what vocabulary studies can reliably show about differences between the sexes in this respect. First, sound sampling of men and women as two groups for any kind of language study is impossible unless one controls adequately for other factors because neither group is homogeneous: educational, class, ethnic, religious, and economic factors interact with gender to create significant differences among men and among women. Second, situations or tests designed to elicit vocabulary range are problematic because the person being tested may well censor his or her responses in the face of particular kinds of interviewers or elicitation procedures. At best what an empirical study can tap is differences between men's and women's observed usage in populations and situations that are in other respects comparable.

Research conducted in the United States, Canada, and the UK on pronunciation differences between women and men has shown that, except in casual speech, women tend to use more prestigious variants than men do. (There are speech communities where this is not the case.) Early quantitative studies selected variants that were known to be prestigious and to have a stigmatized counterpart. The relative frequency of usage of each of the pair of variants was measured among subjects from particular regions, grouped by social class and sex of speaker.

In his well-known study of social class stratification in New York speech, Labov (1972) measured the relative frequency of the presence or absence of postvocalic (r)—its absence is stigmatized—and of the prestigious fricative (th) and its stigmatized

affricate and stop counterparts. There was variation by social class and age as well as gender but one clear finding was that, in careful speech, women used fewer low-prestige forms than men did in all social classes (see *Sociolinguistic Variation*).

Trudgill's findings were similar regarding gender and class stratification in Norwich speech. He elicited data with four different levels of formality, from joke telling at one end of the spectrum to the reading of minimal pairs of words at the other and found that in all social classes women had a lower percentage of stigmatized forms in all styles than men (Trudgill 1974).

Having obtained recordings of his subjects' speech, Trudgill went on to investigate their perceptions of their speech. He played tape recordings of words pronounced in both a prestigious and a stigmatized way and asked each subject to say which his or her own pronunciation most resembled. Subjects' responses were then checked against the recordings of their speech. There were inaccuracies in self-report among both men and women, but the nature of the inaccuracy varied: more men than women 'under-reported,' identifying their pronunciation with the version more stigmatized than their own, whereas women did the reverse and identified with the form more prestigious than the one they used.

Trudgill and Labov offer similar explanations for the class- and sex-related differences in accents. They argue that groups which see themselves as almost within reach of higher social status will use prestigious speech as a means of gaining acceptance to or signaling actual membership of a higher status group. (Those already in high status groups can afford to be more relaxed about their speech.) They think that women may use 'better' speech as a means of gaining entry into a social group of higher status because it is less easy for them to do so on the basis of their own education, work, and earnings, their status usually being ascribed to them on the basis of the education, work, or earnings of their fathers or husbands (see *Social Class*). Moreover, as primary care-givers for the society's children, women are expected to provide good models for children's speech.

But what accounts for the greater identification with low-prestige speech by men? Trudgill explains the apparent anomaly as a product of the operation of two different kinds of prestige, overt and covert. Society as a whole openly recognizes some accents as better than others. In Britain, Received Pronunciation is associated with qualities such as competence and intelligence. At the same time, however, working-class speech is often associated with some highly valued personal qualities such as humor and sincerity. Trudgill believes that it is also associated with the toughness and masculinity believed to be characteristic of the men of that class. Where toughness is thought to be an aspect of 'real masculinity,'

desirable in all men, working-class speech patterns confer covert prestige in that respect. Hence some men of other social classes imitate working-class speech and also perceive their own speech to be more working-class than it is. Clearly, in the study of pronunciation differences, more is at issue than degrees of refinement.

The assumptions and the methodology underlying these and other related studies have been criticized and the value of the findings reassessed. Labov and Trudgill used the common practice of defining a woman's social class by the criterion of the social class of the man on whom she is presumed to be dependent: father or husband. Coates and Cameron (1988) find this anomalous in an age of high male unemployment and single-parent families where women are the only breadwinners. They also challenge the assumption underlying the 'covert prestige' explanation of men's tendency to associate themselves with vernacular culture, namely that this culture is masculine. This assumption has the effect of placing women outside the working class, and of ignoring the specific realities of working-class women in social and labor structures. They claim, moreover, that the studies have obscured the fact that, even within each social class, neither men nor women form a homogeneous group—subgroups arise as a result of differing educational, economic, and social opportunities. They argue that it may well be that it is these which shape pronunciation preferences, rather than broad stereotypical male and female images and roles (see *Stereotype and Social Attitudes*).

It is now felt to be essential to examine the aspirations, opportunities, and experiences of men and women when attempting to explain gender-related linguistic patterns. This kind of analysis allows for the foregrounding of different aspects of an individual's identity and concomitant features of language use in different circumstances. Face-to-face interaction among small groups of people who share work or leisure activities creates solidarity and this affects the way group members speak, particularly in one another's presence. Research methodology based on social network theory focuses on effects of this kind (see *Social Networks*).

Lesley Milroy's study of language and social networks in three working-class areas of Belfast showed that while there was gender-related variation in speech in each area, there were differences among the three male groups and among the three female groups (Milroy 1980). It is clear from her multidimensional analysis of the data that the interaction of age, gender-division of labor, economic and leisure opportunities, and types of social networks is very complex, and that explanation of linguistic variation between and within small groups of people has to take this complexity into account. No single variable has an overriding explanatory or

predictive value. Milroy found that while in all areas males and females use the vernacular as a symbol of their loyalty to the local community, they did not always use the same variables to express this function. A study of working-class adolescents in Reading reveals the same thing: both girls and boys used vernacular features but different clusters of them (Cheshire 1982) (see *Adolescent Peer Group Language*).

Gender-related ability and willingness to use the standard dialect is also quite widely attested. Sometimes a community's expectation that it is proper for one sex to have a command of the standard is strong enough to bring that about before external factors (such as employment) make direct demands on individuals. In other cases the explanatory factor is that the jobs available to one sex require proficiency in the standard dialect, whereas those for the other sex do not. That both explanations may be valid in one community can be seen in Waccamaw Neck, South Carolina, where the language continuum ranges from Gullah (a creole), through Black English to a regional standard English. From the age of 10 onward, girls use more standard English features than boys from the same neighborhood and even from the same family. Ten is the age at which girls begin to be regarded as young ladies and are expected to spend less time playing with their peers (of both sexes) and more time on domestic responsibilities. Employment opportunities and rewards differ for young adult men and women: the best-paying jobs for women are in teaching, nursing, and sales—all of which require standard English, but they pay women less than men can earn in blue-collar jobs, where standard English is not necessary. The combination of social expectations and economic realities thus results in greater use of standard English by females than males between the ages of 10 and 60. In the oldest generation, however, it is the women whose speech is furthest from standard English. In their earlier years these women were illiterate and confined to their immediate community, while the men were economically more mobile and had more contact with standard English (Nichols 1983).

2. Gender-distinctive Conversational Style

Popular notions, often encapsulated in proverbs, express strong beliefs about differences in the quantity, quality, topics, and patterns of men's and women's speech. Coates (1993) provides a rich and varied sample from which the examples below are drawn. A common belief is that women are constitutionally verbose:

Ou femme y a, silence n'y a. (France)
The North Sea will sooner be found wanting in water than a woman at a loss for a word. (Jutland)

Many women, many words; many geese, many turds. (England)

The belief that women talk far too much is closely linked with a belief that what they say is of little importance, if not actually unpleasant or tiresome. This is exemplified in the last proverb quoted above and is captured in many cartoons depicting chattering women and their exhausted spouses. The implication is that, ideally, women should be silent or quietly spoken, and that they should be good listeners, not only in the sense of hearing but also of complying.

That men and women differ in the topics of conversation they choose and are competent to discuss is another commonly held belief. Women are thought to prefer personal topics; men, public issues. Linked to notions about preferred topics are strong beliefs about differences in the ways in which women and men conduct conversations. Men are believed to be better than women at sustaining logical and dispassionate arguments involving complex issues. In dealing with ideas men are held to be clearer and more forceful, and women more confused and hesitant. Women are thought to be able to articulate feelings and intuitions better than men, being more willing and able to find verbal images for the nonrational. The putative differences are often assumed to be a direct result not of socialization and restriction of opportunity, but of innate differences between male and female. Reasons for the belief in (and the results of) differences in language use have been explored both in contemporary psychoanalytic theory (see Sellers 1991) and in empirical research.

Observation of conversations and detailed examination of transcripts have shown differences between men's and women's single-sex conversations, and have also provided evidence of gender-related patterns of behavior in mixed-sex conversation. These are discussed below. It should, however, be noted that the social and economic factors which create differences between and within each sex group affect discourse patterns just as they affect the use of particular linguistic variables. Thus, wide generalizations should not be drawn on the basis of studies of particular male and female conversations. Relatively few of the empirical studies of conversational style were designed to be comparative across age and cultural groups.

In the single-sex conversations that have been analyzed women do indeed describe and discuss their feelings more than men, who prefer impersonal topics such as sport and current affairs. When feelings are expressed men are likely to respond by giving advice, rather than by self-disclosure, which is a common female response. In an article which was based on analysis of real and literary dialogs, Sattel (1983) suggests that by withholding expression of their

feelings, males are concealing their limitations and the resulting image helps them to exercise power. This suggests that the notion of strategy, conscious or unconscious, would not be out of place in an analysis of conversational patterns. The broad gender-related differences in conversational style revealed by empirical studies will now be examined (for more detail see Coates 1993).

Competitive style is more likely to be used by males than by females, whereas the converse is true of cooperative style. The discourse features giving rise to these characterizations are, chiefly, aspects of conversation management. The 'one-to-many' pattern—one person wanting or competing for the attention of all participants—is quite common in all-male groups, whereas in all-female groups there will often be several smaller conversations going on, not competing for center-stage.

Women are more likely than men to do the work of ensuring that conversation is maintained. To do so they use responses such as 'yeah,' 'mhm' to signal attention to what the speaker is saying. They also ask questions or, by means of gesture or glance, invite others to participate, thus easing the movement from speaker to speaker and topic to topic. Men, on the other hand, are typically more preoccupied by the subject matter under discussion and do not give much attention to smoothing the transition from one topic or speaker to the next. Verbal aggressiveness is more common among male than female speakers. One linguistic manifestation of it is the tendency to interrupt. In same-sex groups the level of interruption is relatively low and is similar for males and females. (The level of resistance to interruption is similar for males and females—both tend to concede the speaking turn to the interrupter.) In mixed-sex groups there is a striking gender difference in interruptions. Zimmerman and West found that, whether or not speakers knew one another, and regardless of setting—natural or laboratory—the rate of men interrupting women was far higher than the reverse. In their data the ratio of male to female interruption in a conversation ranged from 63 percent : 37 percent to 100 percent : 0 percent. They argue that interruptions are gestures of power and that taken singly they may be minor, but because they occur constantly they help to constitute women's subordinate status (Zimmerman and West 1975).

Mixed-sex conversations provide evidence regarding the belief that women talk more than men do: the opposite seems to be true. Males 'have more say' than females: in mixed groups, whether of children or adults, it is usually the males' topics that are taken up and developed, males who change topics of conversation, and males who talk more often and for longer stretches than females. It might be imagined that women would take the dominant role in a conversation if they were of a higher social class than the male participants or if they rated higher on some other important criterion, such as expertise. However, male speaking rights prove to be strongly entrenched. A study designed to see whether a high level of expertise in a valued field would confer on women and men the same right to uninterrupted speech showed that it did not: female medical practitioners were interrupted by their male patients far more frequently than were male doctors (West 1984).

If in mixed-sex conversations female speakers are subject to more interruption than males, and if new points that they introduce into conversations are seldom taken up by other speakers, it is hardly surprising that people believe that women cannot sustain or develop arguments as well as men can! And they have not found it any easier to be read than to be heard. A brief but well-documented account of the difficulties faced by women wanting to get their work published is provided by Joanna Russ (1983) in a book entitled *How to Suppress Women's Writing*. She gives a description of subtle and less subtle attempts to silence women with respect to certain topics, literary forms, types of publication, and types of readership. Her ironic, condensed version of the processes makes them seem ridiculous, but her analysis of attitudes underlying them, and the examples taken from reviews, diaries, and letters by writers and publishers are combined in a serious and sobering account of centuries of prejudice and waste.

Many French feminists argue that languages have developed to meet the requirements of men, and do not easily carry women's meanings. They argue that it is primarily through writing that women must seek to break the linguistic bonds that have silenced or distorted their experience. Some feel that ultimately what should be sought is a new language, while others feel that it would suffice to disrupt current syntactic norms and to create new words and new rhythms which give expression to women's bodily experiences and to their ways of relating to other people (see Sellers 1991).

Unfortunately some sociolinguistic research on language and gender is not informed by adequate gender theory or theory of identity construction. In such cases both research design and interpretation of findings are flawed in one or both of the following ways: over-simplification of gender variation (on the assumption that there are universally only two categories—masculine and feminine—which exist in binary opposition to each other); failure to recognize that because gender always intersects with other socially salient factors it is unlikely to be the only factor accounting for observed features of male or female language use.

3. Development of Gender-related Differences in Language Use

The only differences that seem to have a primarily biological base are that first-language acquisition is often more rapid among girls than boys; that boys are more subject to stuttering and dyslexia than girls; and that men have deeper voices than women. Empirical research suggests that the other differences are socially learned (Phillips et al. 1987).

Late-twentieth-century developments in psychoanalytic theory in France locate the beginning of differentiation between male and female relations to language in their differing early psychosexual development. Regarded as crucial by some theorists are the processes of separation from the mother and of identification with the same-sex parent, processes vital to insertion into the symbolic order, which includes language.

How do communities transmit to children their gender-specific norms of appropriate language use? In the opening section of this article mention was made of overt teaching or publication of normative codes, but much of the learning happens more diffusely. Modeling on adults' verbal behavior, noting differences in adults' responses to the speech of boys and girls, participating in peer subcultures —all of these are part of acquiring communicative competence as a boy or girl.

Embryonic versions of characteristic adult male and female discourse patterns can be observed among children, for example adversarial and cooperative styles of organizing themselves in play situations. Some research has focused on how children learn these and other aspects of linguistic behavior. Another approach has been to do a longitudinal ethnographic study of the whole process of learning what it means to speak appropriately as boys or girls in a particular society, uncovering the interaction of a variety of linguistic and nonlinguistic factors that impinge on young children.

Shirley Brice Heath's account of a Carolina speech community suggests that the sex of the child affects verbal behavior toward him or her from very early on and shows young children responding to models of male and female language use in their family and in the community. For example, women are supposed to be able to 'fuss' (which means to bring family and community members' behavior into line) and very young girls are allowed to practice this on adults. Girls are also supposed to know and be able to elaborate a repertoire of intricate skipping and clapping rhymes which they perform as a group. Men and boys need to be able to engage in audacious and amusing verbal repartee, and to have an answer for challenges and reprimands from women or other men. The domain for fussing is domestic. For rhymes it is somewhat more public but it is an all-girls sphere, whereas male speech skills are for public

display. Little boys learn to meet teasing and challenges with sharp verbal responses in the most public area in the neighborhood, namely the 'plaza' at the end of a cul-de-sac. Girls acquire their skills in more private places watched almost exclusively by girls, or as individuals on their own in front of a mirror—a striking manifestation of the contrast in domains considered proper for male and female speech (Heath 1983).

In many societies women have not been entitled to speak in the society's most prestigious public domains. (This is changing in some places but it is still relatively rare to find women preaching, participating equally in political decision-making forums, or being appointed judges.) Schools tend to extend the family and community's expectation that males will and should speak more in public and semipublic spheres. Observation of classroom interaction has identified factors which reflect and encourage this expectation, even when teachers are consciously trying not to give more speaking space to boys: teachers' gazes are more frequently directed toward boys, and boys are more successful than girls in catching teachers' attention by raising their hands faster or calling out. In class discussion groups girls often play the facilitative role in keeping conversation going while boys dominate topic development, patterns that continue into adult life. It is important to note that gender socialization is not over and done with by the end of adolsecence. As people's circumstances change or as they enter a new socially recognized age group they have to learn linguistic and other behavior that is regarded by their communities as gender-appropriate. (They may, of course, choose to disregard the norms in practice.) (See also *Discourse*; *Socialization*.)

4. The Encoding of Gender Differences in Language

The preceding discussions deal with gender differences in the use of language. But what of language as a system? What of the lexicon available to the speakers of a language to describe members of the two sexes—does it embody significant nonbiological differences in the encoding of 'masculine,' 'feminine,' and related terms? And if it does, is there any evidence that this has consequences for the way people are categorized and regarded in practice by themselves and by others? How deterministic is language?

Enormous heat has been generated in English-speaking speech communities by challenges to traditional terms of address for women and to the convention of using the masculine pronoun when referring to persons whose sex is unknown, or to a category including both sexes. In fact, a very common perception of language and gender research among those outside the field is that these are its

central questions, if not its entire scope. This perception is inaccurate, of course, but, as gender-related terms of address and pronouns are so much in the public eye, they will be considered in some detail here.

Many societies use titles which indicate the sex of the person being referred to or addressed. A title may also encode age and, in the case of women, marital status. Surnames and titles are at issue in societies where the terms of address used for females conventionally indicate whether or not the woman has ever married whereas the term for men does not. This lack of parity has raised objections. There was a suggestion in the early twentieth century that another title be created for men so that references to them would also indicate marital status. It seems not to have found many supporters. There are practical problems with marriage-related titles: in spoken and written transactions in business and civil service where the female addressee's marital status is unknown, the possibility of using an inappropriate title is high. Style manuals published in the 1950s for use in the commercial world suggested the use of *Ms* as a title to be used for women irrespective of their marital status. In the 1970s and thereafter, the use of the title was supported by feminists who have a principled objection to women's marital status but not men's automatically being indicated, even in encounters where it is not relevant. They see the convention as one aspect of an ideology that always places women in terms of their relationship to men.

The patrilineal transmission of surname is another. It is common for a woman to lose the surname she had before marriage (usually her father's family name) and to take on that of her husband. The change in the formal term of address for a woman when she marries can be quite thorough: in some English-speaking speech communities it has been proper in formal circumstances to address or refer to a married woman as *Mrs* followed by husband's first name and his surname. For example, *Miss Anne Smith* would, after her marriage, be referred to as *Mrs Reginald Brown*. Some other societies have the convention that the woman keeps her surname and adds her husband's, while the surname of their children is a combination of one surname from each parent. However, the section of the surname that is transmitted from parent to child is the one that came from the father of each of the parents. Strong objections to these patrilineal traditions are made on the grounds that they contribute to processes in and beyond language which mark women as appendages to men, or which render them invisible. Such objections have led women to challenge naming conventions by taking their mothers' names or choosing surnames that come from neither family.

In many languages male forms are used for common gender. The word for 'man' is used in generalizations about human beings: 'the ascent of man,' 'man is the only creature with language.' The use of the masculine pronoun as the common one in languages which have masculine and feminine pronouns extends this practice. This produces sentences such as 'The medical advances made by man suggest that he will be able to extend average life expectancy for mankind even further' which are supposed to cover females as well as males. But do they? The pervasive habits of thought and speech which they embody have been said to create false and damaging impressions of the relative importance of men compared with women. Nonetheless they persist, supported by the argument that, as 'man' and 'he' are generic as well as sex-specific terms, when they are used in generalizations they include women. A second defense is that stylistic awkwardness results from attempts to be more inclusive in the use of pronouns when generalizing. One argument in favor of abandoning the use of masculine forms as generic is that they are no longer truly generic. The status of 'man' as a generic has been gradually eroded. Baron (1986) shows that from the eleventh to the thirteenth century 'man' could be used in contexts in which it would sound odd now. For example, Aelfric could write, in 1000 AD, 'His mother was a Christian named Elen, a very full-of-faith man, and extremely pious.' But by 1752 Hume does not assume that the reader would automatically take 'man' to include women, so, when he intends it to, he indicates this, writing: 'All men, male and female ....' By the 1990s the function of 'man' as a male referent interferes with its ability to serve as a generic—the following sentences sound contradictory: 'As a mammal, man gives birth live and suckles his young'; 'Anne Grey was the first man to row the full length of the Exwy River.' The substitution of 'person,' 'people,' 'human beings,' or 'humankind' for 'man' and 'mankind' is fairly easy to effect, but attempts to create new single-sex pronouns (e.g., 'thon') to replace the masculine as generic have not been successful. The most common practice is to use both, indicating in some way that they are alternatives, for example 'he or she,' 's/he.' The use of 'they' as a third person singular pronoun in cases of general reference is quite common in speech and is starting to be used in writing.

The lexicon of a language provides interesting evidence of gender perceptions. Historical studies have examined lexical entries for the same items over several centuries to show changes in meaning. Attention has also been given to whose meanings were represented, and who the lexicographers were— women or men. Men overwhelmingly outnumber women in this field. There are feminists who claim that men control language but there are also

343

feminists who contest this (see Cameron 1985). A long line of women writers have spoken of their sense that the languages in which they were producing poetry or fiction did not have words to express what they regarded as experiences peculiar to women. Various contemporary French feminists also claim that there are lexical gaps which result in the silencing or distortion of women's meanings. They link the existence of these gaps to fundamental differences in the construction of male and female sexuality.

Miller and Swift's *Words and Women*, and Baron's *Grammar and Gender* give detailed historical accounts of the encoding of gender perceptions in English. Centuries of linguistic evidence that male and female are not simply perceived as different but equal prompts Baron to say, in the introduction to his text, that his compilation of opinions about women and language 'presents what can be viewed as a depressing litany of insults' (1986: 9).

A history of changes in the meanings and forms of words relating to women and men can show something of changing societal realities and perceptions. Agent nouns are a particularly interesting set. In Old English suffixes indicated the sex of the referent: 'er(e)' was the male suffix and 'ster(e)' the female suffix. Words referring to those who baked, spun, and sewed were *baxter, spinster*, and *seamster* as this work was done by women. When men moved into these occupations the word did not always change its form to indicate this: *seamster* could be used for anyone who sewed, male or female. If, however, men became dominant in a formerly female occupation they often took over the job's common designation and new terms were coined to refer to women still in these occupations, e.g., *seamstress*.

Miller and Swift claim that this pattern is one manifestation of the prevailing tendency to regard the referent as male unless indicated otherwise. ('Marking' is the technical term for 'indicating otherwise'—showing that one member of an oppositional pair is restricted in ways that the other is not.) In English, terms that can refer to both sexes are almost always the terms that are used to refer to males, for example *actor, author*. In contrast, terms that are morphologically marked as referring to females (such as *actress, authoress*) are never applied to males. There are a few exceptions to the male-as-norm rule. For example, *nurse* is taken to be female unless indicated otherwise by the use of the prefix 'male-,' giving *male-nurse*. As more men move into the nursing profession this prefix may well drop away.

Markedness is of interest to people concerned with the role of language in maintaining dominant societal perceptions, for several reasons. They argue that, as long as words referring to women and not to men have to be marked for gender, the belief will persist that it is exceptional for women to be in these positions. As long as it is male terms that are also the common gender terms, women's presence will tend to be obscured, as it is by the use of 'man' and 'he' as generics.

Where there are gender-distinct terms, there is not necessarily parity between them. An examination of some word pairs with a common stem and a gender suffix shows that there is a tendency for the word carrying the female suffix to be not only different from but also unequal to its male counterpart, the female form carrying a connotation of relative triviality. For this reason a woman at the head of a bank or a state would not use the form *manageress* or *governess* to refer to herself—the fields of control associated with the female terms are less significant than those associated with the terms *manager* and *governor*. A more explicit reductiveness is manifest in terms that are simultaneously marked by their suffix as female and diminutive, for example, *majorette*.

Comparisons of word pairs reveal not only an association between diminished importance and femaleness, but also what Miller and Swift refer to as 'semantic polarization' and the pejoration of words referring to women. Paired words that might be assumed to contrast with each other only in sex of referent in fact contrast in other ways too, ways that are derogatory to women. The fields of meaning become polarized so that there is little common semantic ground left in the sense in which they are frequently used. For example, the element of control originally implied in the terms *master* and *mistress* is no longer central to both. Nowadays the domain of control associated with *mistress* would probably not extend beyond the activities of her dog (unless she were a *sportsmistress* or a *headmistress* in which case she would have charge of children). In contrast, *master* has retained its association with control in a range of important fields.

As has happened with *mistress*, pejoration of the female term occurs largely through frequent linkages with implications of sexual promiscuity. As examples, consider the pairs *master/mistress, knight/dame, sir/madam*—none of the male terms but all of the female counterparts have connotations of illicit sexual activity for financial gain. In themselves these examples might seem simply to be interesting, but it is argued that they indicate a problematic general tendency to see women but not men primarily as objects of sexual attention, a tendency that makes it difficult for other aspects of women's being to emerge. Studies of insults in several languages provide further evidence of this association: by far the most common form of insult, whether directed at males or females, is a derogatory reference to female sexual promiscuity.

5. Conclusion

The material presented above has shown that there are gender-related differences in the use of language by, to, and about males and females. In shaping them, gender may be neither the only nor the overriding factor. Where males and females are treated differently in language, it is seldom a case of separate but equal: the inequality is an extension of the prevailing power-relations between them in nonlinguistic fields. There is evidence, barely touched on here, of the psychological, social, and material consequences of gender discrimination through language, consequences which can be serious, even if each particular instance of discrimination seems minor. Of course, language can be and has been used to identify and challenge harmful discrimination and the linguistic forms in which it is manifested, and to suggest alternative dispensations and forms. Whether such changes of form are desirable is debatable: they could serve to mask underlying and enduring sexism. On the other hand, by going against the grain, the alternative forms could alert people to unconscious habits of mind and behavior which, once identified and understood, might be willingly rejected.

Language Change and Language Acquisition
E. L. Bavin

Historical linguistics has been concerned mainly with changes that have occurred within languages and language families in the course of their development. However, in order to understand why and how languages change, there is a need to examine the motivation for change as well as the paths of development. For this reason, child language acquisition (see *Child Language: An Overview*), social variation (see *Sociolinguistic Variation*), and the development of pidgins and creoles (see *Pidgins and Creoles: An Overview*) are related topics. They all examine aspects of variation and change. Language

acquisition deals with change in the developing grammar of the individual, while the other two topics examine change within the language system. While there are parallels between changes observed in the history of languages and innovations that a child produces in the course of acquiring a language, the exact relationship between the changes for the individual learner and for the system as a whole is not yet clearly understood.

1. The Child as the Source of Change

Both nineteenth-century and present-day linguists have viewed the child as the major source of change. For example, at the beginning of the twentieth century Grammont pointed out that features of child language reflected the types of historical changes found in languages of the world. Later, particularly in the field of generative phonology, scholars suggested that imperfect learning results as the child acquires the language and constructs a grammar. Halle argued that the child constructs a grammar by induction, and thus may not arrive at a grammar which is identical to the adult's, while Kiparsky discussed sound change as the result of simplification and imperfect learning by the child. Thus one view of language change is that the source is to be found in the process of language acquisition.

Some changes as the result of imperfect learning are plausible. Marked structures in the input language (that is, the language to which the child is exposed) may lead to reanalysis by the child. While the grammar that the child acquires may differ from the model provided, the differences may be minor so that mutual comprehensibility is maintained. However, while observable differences might be assumed to be minor, they may represent larger differences in the abstract grammar of the child. That is, the child may have reanalyzed the linguistic input and thus internalized a grammar that differs from that of the adult. It can be assumed that the language input to the child must provide some impetus for reanalysis by the child. If the reanalysis involves a word order change, the input language would need to have some constructions with a marked word order, that is, a word order that is different from the basic order. Children acquiring the language will extend the contexts for the marked word order from generation to generation, and thus the change is gradually effected, with observable differences between the adult and child productions being minor at each stage. The marked order would gradually become the basic order.

2. Language Change: Stampe's View of Natural Rules

Stampe's view of the acquisition of a sound system is that there are certain phonetic processes which reflect innate properties of the human speech tract. When a child acquires a language there must be suppression of some of these 'natural' processes, those to be suppressed depending on the specific language. Stampe argues that sound changes will occur in a language if the child fails to suppress a relevant process for the language being acquired. While some features of sound change are also features of child language, notably the devoicing of word final consonants and the simplification of consonant clusters, it is not possible to draw parallels between all phonological processes in child language and language change. For example, a young child will often produce a stop in a fricative context (e.g., [tu] for 'shoe'), but in time the child will suppress this substitution. In the history of languages, the substitution of a stop for a fricative (consonant strengthening) is far less common as a process of change than consonant weakening, the replacement of a stop by a fricative (see *Sound Change*).

Other changes cannot be attributed to children failing to suppress natural rules. For example, while many languages lose word final syllables over time, even though this may result in the loss of grammatical information as with the loss of inflections in the history of English, young children often drop the initial syllables of words in their early attempts to pronounce the words of their language. Syllable reduction in child speech is often related to stress. Since an unstressed syllable is perceptually less salient than a stressed syllable, a child will often produce the part of the word that is stressed, leaving out the unstressed syllables. For example, English-speaking children may produce *nana* for 'banana' and *puter* for 'computer.' A Greek child may produce *ate* for *elate* 'come Plural.' Pye reports that young children acquiring K'iche' Maya first produce the final syllable of a word, that is, the stressed syllable. For example, the form *loh* is produced for the adult expression *kawiloh* 'I like it' with *loh* a stressed syllable consisting of the final morpheme (an inflection) and the final consonant of the preceding one. Although Czech has word stress on initial syllables, these syllables are often dropped in young children's speech. What is perceptually salient to a child, then, is the end of the word or utterance or a stressed syllable.

Another example of the problems raised in trying to match children's forms with diachronic change relates to vowel and consonant harmony, both of which should be natural processes following Stampe. Both are found in children's speech in languages, which do not regularly utilize vowel or consonant harmony. For example, the form *tity* may be heard for 'kitty' from an English-speaking child, and *esese* for *epese* 'it fell' from a Greek child. Warlpiri children regularly use *Lalala* for the name *Nangala*; the language uses vowel harmony but not consonant harmony. The assimilation processes may be reflected in only a few words for each child. In those languages

which do utilize vowel harmony processes (e.g., Turkish, Hungarian, and Warlpiri), children seem to have no problem with acquiring the rules. This supports the view that vowel harmony is a 'natural' process, but since there are few reported examples of vowel or consonant harmony developing in a language over time, these child language modifications do not parallel diachronic changes in language. There is likely to be dissimilation diachronically, not assimilation or harmony.

A feature of child language is reduction in consonant clusters. For example, a Greek child may produce *vato* for *val' to* 'put it' and *klito* for *klis' to* 'close it' while an English-speaking child may produce *poon* 'spoon' and a Warlpiri child *naka* for *nyangka* 'look.' Consonant clusters may develop in languages (e.g., homorganic oral–nasal clusters), but there are also examples of clusters being broken up with epenthetic vowels, and of nasals being lost from clusters (e.g., Gurrinji). Such examples do suggest similarities between child language and language change. Overall, however, there is no clear correlation between processes in language change and the suggested 'natural' phonological processes noted in the early stages of language acquisition.

3. Innovations in Child Language

3.1 Lexical and Syntactic Innovations

Children create and produce new forms in the stages of acquiring a language; these forms may be lexical, syntactic, or morphological. They may be the result of missegmentations, as when an English-speaking child treats *behave* as two words on analogy with *be good*, or a French-speaking child treats *l'avion* as two words (*la vion*). Such missegmentations are evident in the history of languages. Children produce novel items to fill lexical gaps, when they do not know a word for a concept they wish to express. These lexical innovations are not arbitrary; rather they are formed following principles of word formation that are available in the language being acquired (Clark and Clark 1979, Clark 1982). For example, the innovation *to broom* for 'to sweep' follows the principle that verbs can be derived from nouns in English (cf. 'to shelve something'). A similar denominalization is noted in a German child's use of *leitern* for 'to ladder' when talking about using a ladder for climbing (Clark 1982: 404). In Warlpiri *ngapa-kurlangu* 'water-belonging' was used by one child to refer to a fish, and this follows a productive means for creating new words in the language. Such child innovations are generally preempted by the conventional words when the child perceives a mismatch between the innovation and the forms used by others. It is clear that adults also coin new words and functions for words as the need arises, and these innovations follow the same principles used by the children; that is, they follow the word formation patterns that exist in the language. While the creations may be short-lived, some may be adopted into the language.

Children's language also reveals syntactic innovations. For example, structures with double tense marking are sometimes heard from young English-speaking children, with both auxiliary and main verb marked. Bowerman, in particular, has illustrated overgeneralizations with dative alternation, as in *Push me the box* (cf. 'Give me the box') and with noncausative verbs, as with *Don't fall me down* (cf. 'Don't push me down').

These innovations indicate that the child is making hypotheses about the language system being acquired; they also reflect a lack of knowledge on the part of the child about the established norms. The assumptions made by the child when segmenting a string of words into meaningful units, or when determining form–meaning correspondences, or when generalizing about a particular structure do not necessarily lead to the right conclusions, and thus there is a mismatch between the adult and child forms. If the innovations persist, there has been 'imperfect learning' of the system. However, many of the innovations *are* short-lived and get dropped from the child's grammar as it gradually approximates more closely that of the adult. Thus there is a serious problem in suggesting that change originates in child forms.

3.2 Morphological Leveling

There are many examples of morphophonemic alternations in paradigms being leveled diachronically, with a semantically unmarked form being used as the basis for the new forms. For example, Bybee (1985) illustrates that in Romance languages the third person stem has often been generalized to other persons. The semantically unmarked forms in a paradigm are generally the least marked morphologically, and for some languages these are the forms that children acquire first. They are also frequently the forms used by children as the basis for innovations. In the process of acquiring a verb paradigm a child will analyze an unmarked stem as the formal expression of a basic semantic notion, and will then add to the stem to show additional semantic components, for example, tense or number or person. The form of the addition will be selected from what is available in the input data. Patterns that apply over a range of items are reinforced and so will be more readily applied to new items; that is, they will be more productive if more frequent.

An example of paradigm regularization is noted in the Warlpiri child's construction of the pronominal clitics which mark the person and number of the subject and object arguments. The established form first person singular subject is *-rna*. The dual form is *-rlijarra* and the plural *-rnalu*. A creation by the

children is the use of *rnapala* for dual. The form *rna* has been selected as the person form throughout, with an added morpheme to mark number; *lu* is the third person plural subject marker, and *pala* is the third person dual subject marker. The second person forms *npa, npapala* and *npalu* reinforce the choice in the first person of one morpheme for person (*rna*) and one for dual (*pala*).

The process of leveling irregularities in a paradigm indicates a general preference for one form–one meaning, that is, semantic transparency. When several forms seem to be available for marking a similar semantic notion, the child may select one of the allomorphs and overgeneralize by applying it to all instances. For example, a Russian child overgeneralizes the feminine gender marker to other genders, and a Warlpiri child overgeneralizes the form of the ergative case used by adults on two syllable words to longer words. The examples all indicate that the child may attribute a meaning (function) to a form that is not identical to the adult's.

4. Similarities Between Child and Adult Innovations

An area in which overgeneralizations are noted in English child language is in the use of the regular past tense form for irregular verbs. Thus the form *bended* might be used for 'bent' and *thinked* for 'thought.' Bybee and Slobin (1982) studied documented historical changes in the past forms of English verbs and compared these with the innovations made by *both* children and adults when producing past tense forms of irregular verbs. They identified three common areas, one being that the verbs most frequently regularized were the least frequent ones. This supports other findings that infrequent items are the most susceptible to change by analogical leveling, while frequent irregular items are more resistant to change. Infrequent items are less familiar, and thus the established norms are less likely to be well known.

Bybee and Slobin also found that the verbs which were regularized most frequently by the children and adults were those which end in /d/ and form their past by changing the final consonant to /t/. For example, instead of *bent* the form **bended* would be produced. It is of interest that a number of verbs which end in /d/ have already regularized in English. For example, the past form of *blend*, is now *blended*, not **blent*. A third finding was that some speakers used innovations for the past tense forms of those verbs which show vowel alternation, verbs such as *ring, sing,* and *swim*. About half of the adult innovations were in the choice of the vowel for the past tense for verbs in this class. For example, *shrunk* (the past participle) was used as the past form of *shrink*. This type of innovation accounted for most of the innovations from the children. This suggests that

the leveling of the distinction between the past participle and past forms for verbs in the class is increasing. Historically, the distinction has already been lost for some verbs. Thus a historical trend is continuing, with young children propagating the changes. A few of the innovations used in the study parallel the historical trend of adding new verbs to the vowel-change class (e.g., **brung* as the past for *brought*). The verbs *ring, dig, sing,* and *fling* are some of those that have been added to this class since the Old English period. These verbs now all form their past by a vowel change.

That children are not the only instigators and perpetrators of morphophonemic change is clear from the fact that the older children and adults were more likely to add a regular past suffix to verbs ending in /t/ that do not change to form the past tense than were the youngest children tested (e.g., **hitted* for 'hit'). Being aware that the form already contains phonetic material of the past affix, the youngest children avoided 'double' marking. This is a strategy found in applying plural marking as well; young children at first avoid adding the plural affix to nouns that already end in /s/ or /z/, although they add the appropriate affix for nouns ending in other consonants. However, the older subjects showed a preference for marking the past tense category rather than using zero marking, another example of a preference for semantic transparency.

5. The Propagators of Change

There are some similarities between the innovations made by a child in the course of language acquisition and historical changes in languages, but as indicated above, this does not imply that the change originates in the process of language acquisition. In order for a language to change, the innovations must be maintained and adopted into the system. Adults may also innovate, as they revise and adapt the system they have acquired as children.

A major problem with attributing the cause of change to the innovations made by the child is the need to explain why only certain innovations are retained, and why they are adopted in a certain period in the history of a language and not some other. Another problem is that children over-generalize on frequent words, but infrequent words are the most susceptible to change diachronically. For example, for infrequent English words which end in /f/, the regular plural /s/ is now used as in *safes*, and *reefs*, but frequent words retain the old plural /v/ + /z/, as in *wives* and *handkerchieves*. Irregular items must be rote learned, but for an infrequent irregular item, which is likely to be a late acquisition anyway, there is more likelihood that an adult will not remember the exceptional form. This accounts for the tendency for adults to regularize, as noted in the regularized forms produced by the adults in the

Bybee and Slobin study. So change may be motivated by frequency, with older children and adults being the propagators of change.

The 'imperfect learning' view assumes that the child is receiving traditional or standard forms and structures in the input, and that there is no variation, so the child is modifying the system. However, the child may be exposed to forms that already show some variation from the assumed norms. That is, both psycholinguistic and sociolinguistic factors must be considered in studies of language change. Labov has argued that the locus for change is later than early childhood; the peer group is the medium through which change is perpetuated (see *Sociolinguistics and Language Change*; *Sociolinguistic Variation*). Young adults adopt forms used by their peers following social pressure to conform. The view suggests that the source of change must be in the language already as a variable form, and the young child is exposed to the variations in the course of acquisition.

Age-graded studies on variation of forms show a pyramid structure; that is, the oldest people use the most traditional forms, some variation is noted in the middle age groups, and more variation in the youngest. As early as 1905, Gauchat, investigating phonological variables in a Swiss village, documented such a pattern. The implication is that one age group provides the main input for the next, so that variations at one age level will become more widespread with the next. While such patterns indicate a change in progress in the language, one needs to be sure that the young speakers will not adopt the forms used by the older people as they themselves grow older, through formal education or other social pressure.

6. Conclusion

There is some relationship between the acquisition process and language change. For example, it is clear that forms that are acquired late are the most susceptible to loss or change (e.g., the relative clause in Turkish). Rules will be susceptible to loss if they are inconsistent with typological features of the language. In addition, as a language is passed from generation to generation, there may be perceptual reinterpretations by the child as well as articulatory substitutions, both vehicles for change.

Semantic change may also be related to the acquisition process. For example, there are many examples from young children's speech to suggest that the form–meaning (or function) mapping for the child is not the same as for the adult. A word may be used with a wider meaning than for the adult (overextension), or narrower (underextension). Diachronically, word meanings change in both directions. If the early meanings attributed to a form by the child are perpetuated, change will result. How-ever, semantic reanalysis is gradual. As the late-twentieth-century research on grammaticalization reveals, lexical items change gradually in both meaning and form to develop into grammatical morphemes.

Frequently there are differences between the young child and adult meaning for a grammatical morpheme. Many cross-linguistic reports indicate that when a child first uses tense morphology the meaning for the forms is aspectual not temporal, since the forms encode information about the nature of the event (e.g., whether completed or ongoing) rather than information about the temporal location of the event (Slobin 1985). The saliency of aspect over tense for the young child as parallels in language history in that aspect markers frequently develop into tense markers. However, this developmental change only parallels diachronic change; it does not motivate it.

The preference for one form–one function in child language is illustrated in analogical leveling and in the use of periphrastic causatives over lexical causatives; for these features of child language there are historical parallels, but this does not imply a causal link. Innovations must be perpetuated for change to take place. The preference for overt forms for semantic functions is reflected in a child's preference to use pronouns in a pro-drop language where they are not required in the adult system, as in Italian. But there is no evidence that the use of overt pronouns by the child is indicative of a change in the language.

Overall, there are problems with the view that all children's 'errors' (or innovations) survive as diachronic changes. Children's leveling of irregularities in morphological paradigms may survive, as many subtle differences in the interpretations of words and grammatical morphemes, and extensions in the contexts for variable structures. Thus some change may be viewed as a consequence of the acquisition process.

However, adults are also innovators. The motivation for innovations from adults is not necessarily the same as for children. While the child is hampered by memory limitations and lack of muscular control (Aitchison 1991), the adult is influenced by the demands of the communicative situation. Slobin (1977) has argued that the needs for the speaker to be quick yet expressive constrain the direction of change. A consequence of being quick leads to phonological attrition which may affect the morphemes in a language, with a resulting reduction in the functional load of a morpheme; another part of the grammar picks up the function to fulfill the need to be expressive. Whether changes are initiated in the acquisition process or by the adult, they may be slowed down or stopped; changes must be tolerated by the speech community if they are

349

to persist. Since changes must be institutionalized if they are to affect a language's history, it must be assumed that the changes are not the result of idiosyncratic learning by a child, but reflect some general processing and communicative principles that influence many speakers in the language community.

Maps: Dialect and Language
J. M. Kirk

1. Introduction

Three broad classes of geographically and demographically distributed information and interpretations are represented by linguistic maps:

(a) *languages* (often in contrast, or in contact, with other languages);

(b) *dialects* (with some externally-conditioned expectation about geographical distribution or borders, which may be known or fixed at the outset);

(c) *geolects* (i.e., linguistic or spatial variation, without any externally conditioned geographical expectation or borders, which may be variable, mapping what the data reveal).

Maps used to represent folk or popular perceptions about dialect areal distribution as in Preston (1989) are not dealt with here.

As the new millennium begins, linguistic maps are undergoing a silent revolution. Over traditional paper copy bound in atlases, the web resources of the Internet medium provide unprecedented opportunities for display, for multimedia interaction, for interpretation, as well as for distribution. Any browser search on key terms such as 'linguistic geography,' 'linguistic atlas,' or 'linguistic map' or their equivalent in international languages of scholarship such as German ('*Sprachgeographie*', '*Sprachatlas*,' or '*Sprachkarte*') or French ('*geographie linguistique*', '*atlas linguistique*' or '*carte linguistique*') already yields hundreds of responses. Maps in full color, databases, and sound files—some compiled in response to the new medium, others digitized from earlier resources—may be downloaded in an instant, regardless of language or dialect, or of place of origin or processing, and are available to end-users conveniently and inexpensively like never before, removing the need for costly publications or for visits to archives or libraries. Wenker's *Deutscher Sprachatlas* is now available at *www.uni-marburg.de/dsa/*; Maurmann's *Karte der Deutschen Mundarten*, reproduced in its original colors, is to be found at *www.heimatvest.de/sprachkarte.htm*. The benefits of color are well demonstrated in Comrie et al. (1996), Goebl (2000), (Graddol (1981)), König (1982), Kunze (1998), Viereck, Viereck and Ramisch (in press).

2. Languages

Maps are an inextricable part of the presentation of information about the number of languages in the world (Crystal 1997, Moseley and Asher 1993). Wurm (1996) and the ethnologue website (*http://www.sil.org/ethnologue/*) show the location of languages which are dying. Maps in Bailey and Görlach 1982 and Crystal 1995 deal with the global spread of certain languages and the increasing globalization of English, especially in countries where it is an official, second-official, or semi-official language, or where its foreign language status is rapidly changing to second language status (Graddol 1997, Hartmann 1996). Such language maps can also indicate types and degrees of societal bilingualism and multilingualism, as in Ryckeboer (2000) on the use of French and

Dutch on the French-Belgian border. Language maps are based on a combination of knowledge of a particular area and fieldwork, as in Breton (1997), Masica (1976), and Wurm et al. (1996) for South-East Asia, or Hock (1986) for Africa, Europe, and Asia. Many such regional language maps are now on the Internet: 'Linguistic Map of Timor Island' at *rspas.anu.edu/linguistics/UabMeto/map.html*, 'Linguistic Map of India' at *www.askasia.org/image/maps/india4.htm*, or linguistic maps of East Africa at *www.urich.edu/~kkasongo/LinguisticMap.htm*. Ethno-linguistic maps of post-war Europe are at *www. multimedia.calpoly. edu/libarts/mriedlsp/History 315/ map3.html*, or of the Caucasus Region at *www. geocities. com/Athens/Parthenon/9860/etnokau.jpg*.

3. History of Dialect Maps

Although an awareness of geographically-conditioned linguistic variation within a language has existed for centuries, maps with a linguistic content have existed only since the early nineteenth century (the first appear to be by J. A. Schmeller and date from 1821; the first map of English appears to be by Prince L. L. Bonaparte in 1876). Such early maps dealt primarily with sounds or words and, until recently, linguistic maps have continued to adopt an individual, item-centered approach, usually showing the reflexes of an older phoneme or the responses to a questionnaire item. They are typified in the *Deutscher Wortatlas*, the *Sprachatlas der deutschen Schweiz*, the *Atlas linguistique de la France*, the *Linguistic Atlas of England*, and the *Linguistic Atlas of New England*. From the outset, there was always an implicit belief that the mapping of sounds or words would assist with an identification of dialect areas, where there would be some correlation between geography and language. There have still been few attempts to do this systematically, or to consider the individual items in groups, or to interpret or to explain or to criticize existing work. Davis (2000) summarizes recent critical work on American English. Geolinguistic maps, which simply map what the data reveal, without regard to physical, geographical, or social factors, are only emerging; in the future, newspaper corpora or, on a larger scale, the national components of the International Corpus of English may also be used. The earliest nineteenth-century maps primarily reveal a concern that the fieldwork upon which they were based was presented with authenticity and faithfulness (hence the popularity of 'documentary maps'). These early maps challenged the prevailing philological doctrine held by the neogrammarians that sound laws knew no exceptions by demonstrating that a study of geographical variation within a language could help to explain historical development for (as expressed by Gilliéson) 'each word has its own story.' The purpose of such maps was the expression of a two-dimensional

statement about linguistic variation which fused, item-by-item, geography with history, and space with time, as shown in Kirk (1985).

Since the 1960s, and increasingly in line with parallel developments in cognate subjects, linguistic maps have been subjected to numerous innovations in cartographical style. Dissatisfaction with traditional methods has led for some time to the grouping together of items on a single map in a much stronger effort to use qualitative data for the establishment of dialect areas, as in the Collective Maps of the *Atlas of English Sounds*. The flourishing of structural linguistics subsequently led to the demonstration that linguistic maps could also be concerned with the mapping of geographically-differentiated linguistic systems and structures, as in Anderson (1987) and Moulton (1960). Recent maps at *www.upenn.edu/ phono_atlas/maps/* show the relationship between production and perception as between distinct or merged minimal pairs, such as *Dawn/Don* or *Mary/merry* in American English. The impact of sociolinguistics has led to a reflection of social dimensions in survey maps as in the *Linguistic Atlas of the Gulf States*, on which see also Montgomery and Nunnally 1998.

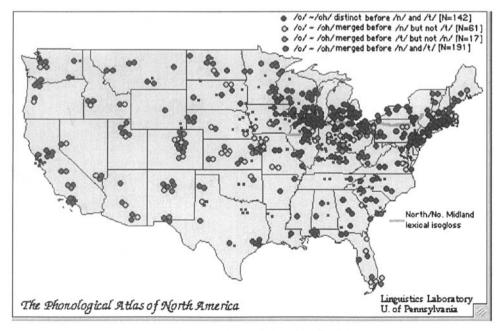
At the same time, maps began to present quantitative analyses and interpretations of the invariably copious data made available by national and regional linguistic surveys. Quantitative approaches have developed in two ways: Davis (1990) and Kretzschmar (1997) apply statistical tests to dialect data; and Goebl (1993, 2000), and Schiltz (1996, 1997) developed dialect-specific tests (generally known as 'dialectometrical tests') including several different measures of 'distance.' These two approaches have culminated in the application of dual and multi-dimensional scaling (see below). Moreover, Bailey et al. (1993), Kretzschmar and Schneider (1996), Trudgill (1983), and Wikle (1997) show how patterns of sociolinguistic variation can be explained by invoking techniques of cultural geography such as diffusion studies and spatial ratios.

All of these approaches have benefited from two concurrent developments during the 1990s:

(a) The resources and capacities of desktop microcomputers now capable of massive data storage, complicated analysis, sophisticated and innovatory graphic displays, and scope for active and instantaneous interfacing.

(b) The world-wide-web for remote accessibility, interactivity, and distribution.

Constant upgrades in bandwidth and networking and huge increases in capacity and speed in desktop processing have led in turn to innovations in, and the sophistication of cartographical techniques.

Nevertheless, publication in book/paper format is likely to continue in the meantime; especially as long-running projects reach fruition. *The Computer*


Developed Linguistic Atlas of England was published in two large volumes in 1991 and 1997; the *Survey of the Gaelic Dialects of Scotland* was published in four volumes in 1994 and 1997; the *Atlas Linguarum Europae* (website at *www.uni-bamberg.de/~ba4es1/ ale-d.html*) published fascicle 5 in 1997; the *Atlant linguitisch dl ladin dolomitich y di dialec vejins* was published in four volumes of maps and three volumes of indices in 1998. Although computer-generating techniques were used in each of these cases and in probably all cases in the future, computer-generated means have created their own paradigm on CD and CD-ROM, led by Bauer et al. (1999–2000), *ALD I-CD: 98 Tonproben zum ALD I/CD-ALD I: 98 campioni fonici per l'ALD I.*, Klemola (in press) for the *Survey of English Dialects*, and Labov et al. in press, developed from their webmaps at *www.ling. upenn.edu/phono_atlas/atlas_chapters/* (see *The Atlas of North American English: Methods and Findings*).

The future of map publication rests beyond any doubt with the Internet, as shown by the Internet maps of the Telsur [Telephone Survey] Project on American English at *www.ling.upenn.edu/phono_atlas/ maps/* (as exemplified in Map 1) and the Linguistic Atlas of Dolomitic Ladinian and Neighboring Dialects (ALD) at *www.sbg.ac.at/rom/people/proj/ald/*, where users are able to interact live and on-line with a database and, with the aid of appropriate retrieval and mapping software, produce their own maps dynamically, upon request, in seconds. Soundfiles of regional or local accents are increasing on the web: see *www.uni-marburg.de/dsa/* for German, or *us.*

english.uga.edu for American English. Haimerl (1997, 1998) discuss his new program for sound digitization and web display; Pennisi (1995) discusses the possibility of web-based audio-*visual* maps.

Dialectologists have traditionally sought to present survey data as clearly, authentically, and as uninterpreted as possible. There are notable exceptions such the *Linguistic Atlas of England*, idiosyncratically interpreted by Orton, or the *Linguistic Atlas of Scotland* (Vol. 3), in which it is not possible to reconstruct either the actual realizations or the incidence of particular phonemes but only the incidence of polyphonemes, but see Johnston (2000) for guidance. From language or dialect 'atlas maps,' the end product of fieldwork-based survey investigations, maps may be 'derived' by phonologists, syntacticians (cf. Gerritsen 1991), lexicographers, or others, for their own specialist purposes.

In these ways, the role and function of linguistic maps has plainly shifted from the original demonstration of the distribution of individual linguistic items (what is specifically known as *linguistic geography*, more specifically *word geography*, and more widely *dialectology*) to the use of geography to explain inherent linguistic variation (what is specifically known as *geographical linguistics* or *geolinguistics*). The qualitative approach of historically-oriented, paradigm-based, item-centered, 'traditional' *dialectology* has now become complemented, 100 years later, with the quantitative approach of sociolinguistics, variation theory, and now *geolinguistics*. Geolinguistics seeks to relate linguistic

Map 1. /o/ ~ /oh/ merger in North American English.

variables and their underlying systems not only with the implicit social characteristics of the speaker's identity (the approach of sociolinguistics) but also with any geographical factors (in the widest possible sense of 'geographical') which might contribute to that distribution and correlation of identity. While more complex than internally-focused historical or comparative philology, the geolinguistic approach is also more realistic, for it correlates qualitative and quantitative analyses of data with qualitative and quantitative analyses of external conditioning factors. The journal *Language Variation and Change* encourages geolinguistic approaches to dialect data (as in the two dialect surveys of Oklahoma and Texas by Bailey et al. (1991, 1993) or in a study of diffusion along the US-Canada border by Boberg 2000). This growing distinction has been made permanent in the name of the subject's international society: *The International Society for Dialectology and Geolinguistics*, launched in 1989, and its journal *Dialectologica et Geolinguistica* which contains many relevant articles, on the dialects of many different languages (*www.uni-bamberg.de/~ba4es1/sidg.html*).

4. Sources of Map Information

Linguistic maps, whether of languages or dialects, usually derive from the material gathered from large-scale international, national, or regional surveys. Durrell (1990) and Schneider (in press) provide alternative overviews, Veith (1989) a full bibliography, and an Internet bibliography is at *staff-www.uni-marburg.de/~naeser/geo.htm*. Further references, including some of the history of linguistic cartography, are to be found in the article on 'Linguistic Maps' in Goebl et al. (1997).

Dialect surveys make use of different methods of data collection. Interviews conducted directly with informants involve the spontaneous oral elicitation of responses to questionnaires or of responses to exchanges in an ongoing discourse usually involving the fieldworker as one of the participants. Ideally, naturally occurring speech is recorded, without the participation of the fieldworker. Montgomery (1993) provides a possible elicitive questionnaire. Several recent phonological surveys are based on telephone interviews, as described by Bailey and Bernstein (1989) and Bailey et al. (1991, 1993) and at *www.ling.upenn.edu/phono_atlas/maps/*. The circumstances of elicitation are usually described in terms of a speaker identity profile and in terms of the elicited speech's speech-act function and of its 'style.'

Data are also gathered by a so-called 'indirect' method, which involves written responses to written questionnaires. The use of written data (especially the elicitation of 'funny spellings' to suggest a local pronunciation) as well as different practices for transcribing spoken data orthographically have not won universal approval and are usually regarded as less reliable, as discussed by Francis (1983, 1993).

Dialect maps are thus derived from the information gathered in their data sources: transcriptions made by the fieldworker in location and any accompanying notes; or edited versions of such transcriptions; or there may be tape-recordings as well as transcriptions; or there may be solely written records. Some maps have been produced from published versions of basic material or from previous maps.

5. Properties of Linguistic Maps

Linguistic maps usually have certain characteristic properties:

(a) They use an *areal base map* which includes some combination of physical and/or administrative details, internal boundaries, or the location and names of major urban centers, or the inclusion of rivers and mountain ranges, all of which are excluded from multidimensional scaling techniques of analysis (see below).

(b) They use *graphic coding devices* for the representation of the particular data in respect of places and/or areas predicted by the map or inferred by the reader.

(c) They use specifically chosen *localities* for which information is presented so as to predict some underlying reality for the linguistic structure of the area as a whole.

By these characteristics, linguistic maps are inherently two-dimensional constructions in which the graphic coding superimposed on the base map enables the prediction or inferring of a relationship between language and geography.

'Atlas maps' (i.e., graphically coded base maps in respect of all the localities) have several further characteristics:

(a) They are *diatopic* because they represent recognizable spatial (or areal) distributions to the exclusion of other primary forms of organization. Linguistic maps usually come to foreground a region or area in revelation of a hitherto unknown distributional pattern showing or predicting relationships of propinquity not just between localities and other localities, but between each individual locality and the area as a whole.

(b) They are *synchronic* because the data represents one period of time (usually the present day or a delimited period in the past, as in the period atlases of English: the *Linguistic Atlas of Late Medieval English*, the *Linguistic Atlas of Early Medieval English*; the *Linguistic Atlas of Older Scots*, as discussed in Williamson (1992–3), Laing and Williamson (1994) and Smith (1992), or in the papers on historical

dialects by Fisiak). Depending on the coding and its intended relationship to the data, maps can offer historical interpretations to present-day data from which the source and direction of internal linguistic development within the area can be inferred. A good diachronic map of the linguistic-historical as well as geographical development of European words for 'cucumber' appears in Hildebrandt (1993).

(c) They are usually *monosocial* because the data usually represents only one social group or indiscriminately social because no attempt is made to discriminate between the data's inherent social values and because of difficulties of multivariate cartography. Expanded locality slots present social variables alongside linguistic variables in the *Linguistic Atlas of the Gulf States* (Vols. 6–7).

6. Base maps

Base maps show only the geographical position of the localities, which have been surveyed. In the case of the *Linguistic Atlas of Scotland*, for instance, the user must realize that the Lowland Scots-speaking area did not extend to the mountain regions of the Highlands and beyond, or to the Gaelic-speaking islands and West Coast; or that in the *Atlas Linguistique de l'Est du Canada* and *Atlas Linguistique du Vocabulaire Maritime Acadien* (cf. Cichocki et al. 1997) all the localities are maritime. Location identification is usually carried out within an administrative and/or physical context, although the *Linguistic Atlas of the Gulf States* and the *Linguistic Atlas of the Middle and South Atlantic States* (as in Kretzschmar and Schneider 1996) create their own areal subdivisions as 'zones' and 'sectors' to facilitate quantitative analyses (e.g., same numbers of informants or population in each zone). The base map of the *Dictionary of American Regional English*, or Bailey and Görlach's (1982) map of English as a World Language (see *New Englishes*) are 'distorted' to reflect demographic factors whereby the size of each state or English-speaking country is presented respectively in proportion to its population. Demographic shifts of English/Creole speakers in the seventeenth century and since 1700 are mapped in Holm (1984).

In the representation of localities, there are several current practices:

(a) *reference numbers* set on a background with considerable topographical detail (usually colored), the numbers remaining visible after the insertion of data, as in the *Linguistic Atlas of the Pacific Area* or the *Südwestdeutscher Sprachatlas*. In future, because of the enhanced capabilities of computer graphics and web resources, there is likely to be greater use of ordinance survey brown-and-green contour maps as base maps.

(b) *pin-point size dots*, usually where there are a great many localities ('dot maps'), the dots becoming substituted by the insertion of data, as in the *Atlas linguistique de la France*, or the *Sprach- und Sachatlas Italiens und der Südschweiz*.

(c) *individual character slots* on the screen of a computer monitor where the lines and columns of the screen are used as a grid ('plotter grid maps') with the slots (like the dots) displaying a symbolic (usually character letter) representation of the data, and the constellation of slots mnemonically configuring the whole (or part) of the survey area, as in the *Linguistic Atlas of the Gulf States*.

(d) *schematic configurations of lines and columns* ('matrix maps') which can accommodate any part of the whole area, ranging from one of four zones (which run in an east to west direction), to individual states, or to the much smaller county-based sectors within states and which can also organize the data automatically. These charts inevitably depend on the full-scale map for recognition of their abstracted configuration. There is also the 'expanded matrix map' where each locality slot becomes expanded into its own multiple slot grid to accommodate a range of responses (such as synonymic responses to the same item), as in the *Linguistic Atlas of the Gulf States*.

(e) *open circles* (often disproportionately enlarged) which are then 'filled' by color or hatching and function as variants on the 'dot' and 'matrix' methods, as shown in Kirk et al. (1994).

Because of their compatibility with a conventional physical base map, circle maps are probably more realistic than matrix maps.

7. Map Data

Several types of data have qualified as objects of study for representation of linguistic maps:

(a) Different regional varieties within a group of languages, which maps the areal distribution of a country's numerous indigenous languages, as in the *Linguistic Atlas of Kenya* or in *The Atlas of Languages* (Comrie et al. 1996).

(b) Different regional varieties within a single country (not necessarily identical with the entire area where the language is spoken), as with the areal distribution of German's numerous dialects as in Wiesinger 1982–3 or of the traditional and modern dialects of England as in Trudgill 1990.

(c) Individual *features* especially sounds, words ('lexemes'), synonyms (i.e., different responses for the same onomasiological concept), meanings (including distributions of different senses of the same word), word forms or other morphological variants, syntactic variants, and in the case of historical dictionaries, spellings.

(d) Responses to questionnaire-elicited attitudes towards language within an area, as in the *Hessischer Dialektzensus* (Dingeldein 1989).

8. Qualitative Mapping Techniques

Linguistic maps make use of different types of cartography depending on the data, the analysis desired, and the kind of semiotic statement intended. Two types of qualitative linguistic maps are conventionally distinguished:

(a) so-called 'basic,' 'direct,' 'raw-data,' 'locality,' 'uninterpreted,' 'display,' or 'documentary' maps, which focus primarily on the presentation of the data ('the French method');

(b) 'areal,' 'analyzed,' 'interpreted,' 'predicting,' or 'interpretive' maps, which focus on making explicit the regional distribution of the data ('the German method'). A subtype of 'interpretive' map is the 'derived' or 'explanatory' map, which focuses on explaining why the data and the distribution are coinciding where they do.

8.1. Documentary Maps

Documentary maps are a traditional type of map in linguistic geography. Based on the identification of individual localities, they are sometimes referred to as 'locality maps.' They make use of two styles of cartography: the *text map* and the *symbol map*. The function of such maps is to display the occurrence of data at the appropriate localities without further interference by the map maker and without interpretation, leaving readers to draw their own inferences about the geographical distribution of any 'historical,' 'systematic' or 'structural' relationships which might exist in the data.

8.1.1 Locality Text Maps

In a *locality text map*, genuine 'text' (words or phonetic transcriptions) is superimposed 'directly' at each locality. This technique is regarded as being highly objective for it represents the data in question directly and 'honestly' because it is uninterpreted; it is sometimes called the 'raw data' or the 'French' method (because of its widespread practice with linguistic maps of French, as in the *Atlas linguistique de l'Alsace* (Coseriu 1979, Geisler 1993). A recent example for England is Britain 1999 where different

parts of the country are labeled with the outcomes of a merger. The disadvantage of text maps is that it is hard to infer the data's regional distribution. Although the desire for interpretation and explanation has led to more complex maps, this method of presentation occurs with several computer applications, as shown by Davis et al. 1989. This long-serving technique has found a new context in the maps derived from multidimensional scaling techniques.

8.1.2 Locality Symbol Maps

In *locality symbol maps*, 'symbols' are superimposed beside, within, or in substitution of, the locality dot or marker. These symbols represent the actual data via a legend of correspondences and usually comprise geometric shapes, sometimes in different colors. This technique is regarded as objective; although it appears merely to substitute the data, the selection of symbols requires preparation and pre-interpretation; it also allows for some submerging. The great advantage of the symbol style is its clear overview both of the symbols themselves and their distribution. This method is sometimes referred to as the 'German' method (because of its widespread use in maps of German as in the *Sprachatlas Bayerisch-Schwaben* or *Wortatlas der kontinentalgermanischen Winzerterminologie* or in other German-inspired atlases such as the *Dialect Atlas of Carpathia* as described in Siatkowski (1991) or the *Linguistic Atlas of Eastern Nepal* as described in Winter (1993)) and also occurs with several computer applications, as presented by Kelle (1997) for the *Südwestdeutscher Sprachatlas* or by Kretzschmar (1996) and at *hyde.uga.edu/atlas* for the point plotter for the *Linguistic Atlas of the Middle and South Atlantic States.*

8.2. Interpretive Maps

Interpretive maps are also a traditional type of map in linguistic geography. They are concerned with the identification of areas on the basis of contiguous localities, which share identical linguistic forms; they are sometimes referred to as 'area maps.' The function of interpretive maps is to display explicitly the distribution of areas, which share the same response data. Like documentary maps, they also make use of the text and symbol cartographical styles but, in the coding of the areas, interpretive maps make use of two further graphic devices: lines and hatchures. In the interpretation of areas, this method involves some interpretive interference by the map maker, sometimes leaving the map user with quite decided distributions, as in the *Linguistic Atlas of England,* but criticized by Graddol (1981: Map 24 and overlays).

355

8.2.1 Area Text Maps

In *area text maps*, localities with identical responses are regarded as forming contiguous areas, into which genuine 'text' is superimposed to represent the data. The areas so formed are established by circumference lines and may be left blank (except for the 'text') or filled in with hatching (and related to the data via a legend). This method is used in Upton and Widdowson (1996) and in Parry (1999).

8.2.2 Area Symbol Maps

In *area symbol maps*, localities with identical responses are regarded as forming contiguous areas, into which symbols are superimposed to represent the data. The areas so formed are established by circumference lines and may be left blank (except for the symbol) or filled in with hatching (and related to the data via a legend), as in the *Linguistic Atlas of Scotland* (Vols. 1 and 2). This method is particularly useful for the use of complex symbols depicting systems or structures or some other aspect of complex internal variability, for use of multiple symbols showing different variables for each locality as well as different realizations for each variable, as shown by Kallen (2000) for Ireland and Ryckebeer (2000) for Dutch-speaking France. Because of its tolerance of overlap, hatching is often used to represent co-occurrence, but the superimposition of four or more hatchures has the danger of illegibility.

Text and symbol styles are sometimes combined to form a continuum between more or less abstraction—which style is chosen depending on the quality and quantity of the data, as shown in Glauser 1974, 2000.

8.2.3 Area (or Regional) Pattern Map

In the 'area (or region) pattern map' in a speciality of the *Linguistic Atlas of the Gulf States* where the entire area is subdivided into six land regions: Highlands, Piedmont, Coastal, Plains, Piney Woods and Delta, as well as numerous subregions, one of which is always the focus of the regional pattern map. In addition, each map combines four separate items, which occur predominantly in the chosen area and are thus highly characteristic features of it. 'Regional pattern' maps invert conventional mapping processes: usually items are first mapped individually, and the consequent distribution is presented; here, a region is first selected and four of the prominent features of the region are mapped for it and all other regions, thus showing the distribution of those regionally characteristic features. According to Kretzschmar (1998), 'area (or regional) pattern maps' show 'chosen' or 'attributive' or 'locality' dialects. The choice of items in LAGS is evidently subjective, in that only the editors could inspect the individual distributions before making a choice. Although the

map has been constructed around the project's individual localities, it is able to link together contiguous areas of distribution and join them up using different hatching styles.

8.2.4 Qualitative Line Maps

If lines are used to delimit identical responses in a single and seemingly contiguous area, such interpretive maps are sometimes referred to as 'line maps.' 'Line maps' are intended to display discrete areas which do not overlap. If the areas do overlap, the lines inevitably intersect. As far as the interpretation of lines is concerned, there are several contrasting possibilities:

   (a) the line is viewed as a perimeter boundary; because it encompasses 'identical language,' it is sometimes called an *isoglosses*;

   (b) the line is a midway point between two responses; because it contrasts 'different language,' it is sometimes called a *heterogloss*. Occasionally, these terms have been interchanged.

A third definition is of the line as 'the midpoint of a transition zone' is given in Chambers and Trudgill 1998.

The actual location of lines has been shown to be problematical. The function of lines drawn on maps is to make the distribution of the mapped data explicit in terms of the whole area. Almost none of the existing studies conceptualize the line as a fixed point, preferring to interpret the line as indicative of a sizeable area where the change from one linguistic form to another is assumed to be gradual. Good demonstrations of the issue include the various narrow and wide distributions for 'frightened' presented in Graddol (1981: Map 24 and overlays), the alternative isoglossic and algorithmic mappings of *piggin* (as a synonym of *pail* and *bucket*) in Kretzschmar (1992), and the interrelationship between lines and symbols in Glauser (1974), revisited in (2000). Further analyses are presented in Davis et al. (1997). Occasionally, lines can be given a directional interpretation, i.e., that such-and-such a line represents the northern or the southern limits of a particular item. As a perimeter, however, the line further suggests that the area on its far side does not have the particular form.

Whether the outer limits of variants are to be interpreted as 'perimeters' or 'boundaries,' different lines may represent the dynamics of change within a speech area (insofar as the progressive development of change can thereby be reconstructed). By identifying the outer limits of progressive stages of development, lines can be interpreted as charting the course of diffusion of linguistic innovations from 'active' areas (where innovations have arisen) into 'passive' areas (where they are received).

Because unrelated items can have the same regional distribution, lines for different data can occur in the same place, i.e., 'in bundles.' An accumulation of similarly located lines is usually taken as evidence of a dialect boundary, although it is far from clear exactly how many isoglosses are required for a bundle—occurrences of single features seem hardly sufficient. The concept of 'line bundles' has led to different suggestions for counting and weighing them, thus establishing different degrees of line strength: the more lines, it seems, the stronger the boundary. This 'heteroglossic' method is used to establish dialect boundaries in the *Linguistic Atlas of Java*, or in Goeman et al. (1993) and other studies of Dutch dialects, or with the selections of *Survey of English Dialects* phonological, lexical, and morphological materials in Viereck (1985a, 1985b) or in Elmer and Rudin (1997) and Elmer (1999). There still remains, however, no explicit or well-justified criterion for grading isoglosses or heteroglosses or for their reliability.

8.3 System Maps

Not all atlas-oriented dialectologists see the construction of 'systems' as their task or goal, so that it is rare to find 'system' maps (typically 'derived maps' or 'process maps') in atlases.

For the 'specialist,' it is considered no longer sufficient or adequate to produce documentary or interpretive atlas maps of individual items. Rather, the identification of different dialect areas depends on maps displaying entire systems, together with their internal structure, because it would be on the basis, not of items, but of differences of exponence within systems, and of the consequent differences in the structure of equivalent systems, that dialects would be seen to vary and therefore to be distinguished and distinctive one from another. Such maps as have been produced from the *Survey of English Dialects* data are published in Glauser (1985a, 1985b, 1986) and Anderson (1987).

In future, there are likely to be only more maps offering 'systematic' or 'structural' interpretations.

9. Quantitative Mapping Techniques

9.1. Quantitative Text and Symbol Maps

Quantitative analysis has hitherto taken two overall approaches: the application to dialect data of general statistical tests and the application to dialect data of new tests specifically devised for the purpose of identifying structural patterns within the corpus of data gathered for a particular area as a whole. Quantitative maps differ from qualitative maps in that they use documentary and interpretive styles to present numerical information. There is almost no uniformity of practice. A useful critical overview appears in Schneider (in press).

There are several documentary approaches:

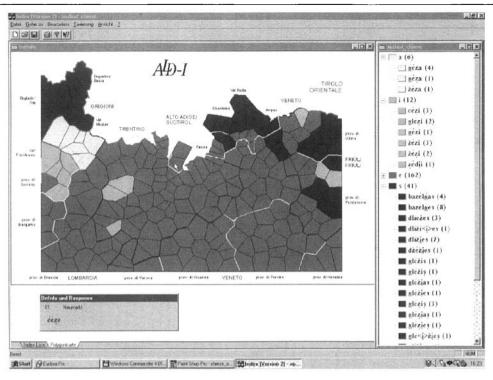
(a) The *choroplethic* approach, which inserts numerical information into the fullest space available contiguous to the locality, as shown by Goebl (1993) and in Map 2.

(b) The *circles* approach, where the circles are colored or hatched whereby numerical information is inserted into locality circles and displayed by hatching, as in Kirk (1994).

(c) The *pie-chart* approach, as in the *Atlas linguistique de l'Est du Canada*.

(d) The *binary* approach, whereby the circles express a binary numerical choice (1 or 0) to express the presence or absence of a feature, as in the *Linguistic Atlas of Scotland*, Vol. 3.

(e) The *plotter grid* and *matrix map* approaches, where the locality slot on the screen is used to display numerical information, as in the *Linguistic Atlas of the Gulf States*.

Sometimes the representation of distance has been done 'directly' by insertion of numerical values on the map or the combination of insertion with hatching within locality circles. Other approaches, based on cluster analysis, use tree diagrams or dendograms to display the distribution of localities, as in *Linguistic Atlas of the Gulf States*.


9.2 Quantitative Line Maps

Since the mid-1980s, lines have been quantified and given a numerical value, leading to the new concept of *isopleth*, where each line has a value, and for each value a line is drawn (rather like contour lines on a physical map), as shown by North (1985) and Thomas (1993).

Between two isopleths, there are constant values, but neither the distance between the isopleths need be regular, or the area uniform. Because isopleths represent numbers, their interpretation points to the source and direction of the linguistic development. The nonlinear, nonwave shape of the isopleths is further interpreted as a good instance of sound change in progress, reinforcing the observation that sound changes in progress jump from one urban center to another and miss out intervening areas. Using phonological material from Dutch, Wattel (1990) and Goeman et al. (1993) propose mathematical models which draw isopleths at different proportional intervals. The resulting maps show the rate of adoption of numerous innovations from an active area into a passive area so that, over a longer timescale, the lines might be thought of as forming a succession of steps over a very broad area.

9.3 Dual-dimensional and Multidimensional Scaling Maps

Cichocki (1988, 1989) creates a fresh paradigm for linguistic maps known as 'dual and multidimensional

357

Map 2. Plural endings of *Chiese* ('churches') in the *Atlant linguistic dl ladin dolomitich y di dialec vejins I.* © Roland Bauer 1999 http://www.sbg.ac.at/rom/people/proj/ald/ald-home.htm (reproduced with permission).

scaling.' Scaling techniques are used to plot locality references on a graph, and are thus quite different from conventional 'physical' maps. The relationship between the locality references is a linguistic and not a physical one (i.e., if locality references cluster together, they reflect places with the closest linguistic similarity). The user has to decipher the references to discover the geographical position of the localities. In a study of material from the Survey of English Dialects, Labov (1992, repeated in 1994) uses multi-scaling both to chart the diffusion and direction of sound change through the lexicon. By using multiscaling techniques, Labov is able to show that sound laws work through the lexicon at different rates so that, eventually, all environments will be affected and changed, thus vindicating, on the grounds of lexical diffusion rates and time, the sound-exceptionless laws of the neogrammarians. Ainsaar and Ross (1993) present another approach. A critical overview of multidimensional scaling is provided by Chambers (1997).

10. Dialect Areas

While dialect areas have traditionally been inferred or predicted on maps, on the presence or absence of a small number of selected key features, speakers have always constructed their own subjective dialect boundaries and formed mental maps about language and linguistic distance. It has, however, never been established scientifically *which* features are the key features, or *how many* such features are necessary. In the identification of one area from another, some boundary lines are more important than others, usually for nonlinguistic reasons. Despite a century's intensive research, there is general agreement that dialectologists are still a long way from establishing objective procedures for the measurement of linguistic difference, divergence and distance, as discussed by Hinskens et al. (2000).

The identification of dialect areas has been considered as the goal of dialect research, in an attempt to substantiate the judgments about their existence made by speakers. There is, however, no agreement about either the nature or the number of features necessary to establish a dialect area in its own right, and it seems dubious that this can be done by dialectometrical techniques as currently developed. At best, dialect areas can be established on the basis of the sufficiency of a selection of features, so that the concept of a 'dialect area' is a convenient fiction. The best dialect maps are not therefore maps of dialect areas but of dialect features, for it does not appear possible to do better.

358

Some refinements to the idea of absolutism of 'dialect area' have led to the discrimination on maps by cartographical techniques of 'focal areas' with 'transitional areas.' Even these, however, are arbitrary and have never been identified systematically. There is no reason why one set of features should count for more than another.

11. Explanatory Factors

Dialect areas are justified in terms of external geographical, historical, political, administrative, social, or cultural criteria with which they are associated and thus established. As the internal discrimination and criterial foregrounding between features for dialect identification are arbitrary, explanations for the particular location of isoglosses are inevitably external.

Physical geographical features are relevant only insofar as they influence developments by impeding or promoting social intercourse, or by coinciding with other borders; few important linguistic boundaries fall precisely with them. Rivers and mountain ranges as well as dense forests and marshlands have recurrently coincided with dialect boundaries. An effective demonstration of this relationship between language and physical geography has been made by the use of topographical overlays for mountains regions, plains, coastal areas, and the Mississippi delta area in several volumes of the *Linguistic Atlas of the Gulf States*.

If linguistic diversity has been caused by the differential diffusion of linguistic innovations, linguistic borders may be the result of historical movements or settlements into, or between, which innovations have not spread. Many linguistic divisions reflect historical settlement patterns and population movements. But total identification of modern dialect regions with historical settlement areas is clearly impossible and developments cut across them. Dialect areas in Germany are considered to reflect settlement patterns of Germanic tribes, just as dialect areas in England can be shown to reflect the Scandinavian settlement. Those in the US are also considered to reflect later immigration and settlement history there, and indeed formed the basis of much of Kurath's research in the eastern US. Postmedieval political boundaries have also influenced the identification of linguistic boundaries. The Scottish-English political border ranks as a very strong linguistic boundary, whereas other boundaries, as between Germany and Denmark or between Germany and The Netherlands, tend to reflect an unbroken dialect continuum. By contrast, geolinguistic maps are arbitrary with regard to the above criteria (but cf. Goebl 1996).

Explanatory maps might make greater use of base maps, which include the details of external influencing factors. Although geographical and historical boundaries have all influenced the diffusion of linguistic innovations and the formations of areas of relative linguistic homogeneity insofar as these are crucial to the establishment of geographical sociocultural groupings, it is just as likely that linguistic diversity has emerged through the desire to be identified, through linguistic behavior, as belonging to one sociocultural group and not to another. For this view, present-day isogloss patterns result from various historical stages of such processes. It is impossible to disentangle social factors in the description and explanation of linguistic variation. This recognition led to their incorporation in the *Linguistic Atlas of the Gulf States*.

The strongest case for the depiction on maps of explanations of regional linguistic variation possibly rests with an accumulation of these criteria, including innovating social tendencies and the growing urban influence on the surrounding rural hinterland or on the adjacent urban areas but excluding the hinterland in between, the one correlating and reinforcing the other. There is no doubt that a multiplicity of factors underlying linguistic diversity, but as these are difficult to establish, the boundaries are sometimes fluid.

As this article repeatedly shows, although not using the social geographer's terminology, many objections to traditional dialectology have been met by the *Linguistic Atlas of the Gulf States*. There are answers to the challenges about the percentage of speakers using particular forms; and how often they use them; there is automatically retrievable, mapped, information about the age (people over or below the age of 65), sex, ethnicity, and level of education (up to tenth grade or beyond it) of the speakers; there is information about synonymic or allophonic variation in relation to all these social variables; and so on. It is unlikely that anybody would seriously commence a large-scale survey these days without explicitly taking situational and stylistic factors into account, or without studying the dialectological as well as the sociolinguistic and geolinguistic methodology of the *Linguistic Atlas of the Gulf States*—Vol. 7 maps the predominant social variables and their correlations with particular lexical, morphological, and phonological features and seeks to show how certain combinations of these sets of variables predominate in particular parts of the LAGS territory.

12. Conclusion

No atlas is complete in itself, and derived studies will always be needed. As Trudgill (1983) argues:

> Dialectologists should not be content simply to describe the geographical distribution of linguistic features. They should also be concerned to *explain*—perhaps, more accurately, to adduce reasons for—this distribution. Only in this way will we be able to arrive at an

understanding of the sociolinguistic mechanism that lie behind the geographical distribution of linguistic phenomena, the location of isoglosses, and the diffusion of linguistic innovations. [my italics]

Dialectologists, who typically investigate map features, can only be encouraged to produce more *explanations* of the distributions of their investigated features in the future.

Four characteristics of linguistic mapping stand out at present:

(a) dialectologists map features rather than structures or systems;

(b) the computer is now prominent and is rapidly becoming exclusive as a graphical and especially cartographical tool;

(c) the Internet is a convenient means of distribution and accessibility;

(d) traditionally-trained dialect geographers are showing a willingness to extend and revise their techniques by incorporating helpful insights from sociolinguistics, social and cultural geography, and other neighboring disciplines.

Better-drawn maps are now being produced, and explanatory maps are emerging. Linguistic maps remain a central resource in linguistic geography, for they enable their users to access, present, analyze, interpret, and explain their data. A map's usefulness as well as its purpose and value are repeatedly reiterated and vigorously defended. With these reaffirmations and the widespread use of microcomputers, map users may expect the linguistic map to remain center-stage for a long time to come as a productive and indispensable research resource and tool in dialectology offering ever new understandings about the nature of regional linguistic variation or about the distribution of languages.

Social Class

M. W. Macy

Although social class is one of the key sociological concepts in language studies, there is little agreement or clarity about the meaning of the term. Linguists frequently research class differences in speech, syntax, and grammar without their criteria for classification, leaving unspecified the underlying social causes of the variations they report. For Marxists, class refers to ownership or control of the means of production (factories, land, tools, etc.), with the fundamental cleavage dividing the owners and managers of large corporations from the class of proletarian wage earners. Other theorists use class to refer to unequal bargaining positions in markets for labor and capital, with the population stratified along

multiple and cross-cutting dimensions of inequality rather than sharply divided into polarized groups. The causal order is also generally unclear; do distinct class voices reflect material divisions that correspond to class inequalities, or do material circumstances reflect differences in the possession of language skills and styles required for upward mobility? Finally, is the distinctive language of the lower classes indicative of cultural deficit and deprivation, or do such claims reflect the class bias of the scholars who advance them? These controversies have been particularly sharp surrounding the eminent work of Basil Bernstein, perhaps the foremost theorist of the language of class (see *Code, Sociolinguistic*; *Bernstein, Basil*).

1. From Static Taxonomy to Historical Change

References can be found in both the scholarly and popular literatures not only to blue-collar workers but also students, the aged, the handicapped, ethnic groups, women, welfare recipients, and renters as subordinate classes. At a minimum, the term class implies only that certain people share a distinctive attribute of interest to the observer, hence the diverse assortment of people who find themselves 'classified.' While Marxists emphasize property relations as the defining attribute, others include knowledge and skill, authority, and more recently, power and cultural capital. Some see class inequality as evidence of injustice, the monopolization of valued resources by a privileged minority. Others see class differentiation as a natural and highly functional expression of individual differences in taste and talent.

These diverse usages should not tempt us to search for an inflexible formula or authoritative definition that might give the term greater coherence. Models of the class structure are not descriptive typologies or taxonomic schemas but rather theories of social and political contestation and historical change. A social class is more than a category; each grouping implies a corresponding theory about the importance and unequal distribution of the defining attribute. Hence, there is a need to examine the origins of fundamental inequalities in the social division of labor and the processes that perpetuate them. The reader can then use and interpret the term more effectively, particularly in sociolinguistic applications. Special emphasis will thus be placed on the role played by language—how these inequalities are manifested in distinctive voices and how these in turn promote, attenuate, or alter the reproduction of class inequalities over time.

2. Class According to Marx and Weber

Marx devoted a lifetime of intellectual labor to unraveling what he saw as the central paradox of human history: humans must work in order to live, yet the more they labor, the stronger become the forces that compel them to work. The problem centers on the alienation of propertyless producers from the means of production they create and on which they depend for survival. The products of their labor belong not to them but to those who own the land, factories, equipment, tools, and materials, all of which are themselves products of labor but now confront their makers as something hostile and alien. In Marx's Hegelian language, the creative process is turned upside down in an inversion of subject and predicate such that 'man's own deed becomes an alien power opposed to him which enslaves him instead of being controlled by him' (1978: 160). In capitalist production, the dependence of the propertyless proletarian on the means of production owned by capital also leaves the worker unable to command remuneration for a day's labor commensurate with what the capitalist could obtain in selling what the worker produced in a day. Reduced to homogeneous raw material, the producers are themselves consumed by the very productive forces they have created. In brief, the workers forge their own chains.

Indeed, the producers are dominated not only by the means of production but by all that they have produced, including politics and religion. The creators of God are thus banished from the real world to the garden of Eden: the more of himself man attributes to God, Marx writes, 'the less he retains in himself. The worker puts his life into the object, but now his life no longer belongs to him but to the object' (1978: 72). Similarly, the dependence of the producers on the propertied class for survival causes the economic interests of that class to take on the appearance of the universal interests of society, the interests that are in turn sanctioned by the state, even when it is democratically controlled. As the embodiment of this universal interest, 'the executive of the modern State is but a committee for managing the common affairs of the whole bourgeoisie' (1978: 475). Contrary to what is often crudely portrayed by his critics, no conspiracy by a prescient ruling class is implied by Marx's famous dictum. Nor are the masses brainwashed by the bourgeoisie. While 'the ideas of the ruling class are in every epoch the ruling ideas,' their dominion is always subject to contestation. The antagonism of interest between the propertied class and the producers creates the material basis for often bloody class struggle, with the potential to transform the property relations that are the root of the conflict.

Marxists in the late twentieth century, faced with the embarrassment of classifying salaried managers and professionals as wage-earning proletarians, broadened the meaning of relationship to the means of production to include both ownership and control (Wright 1979). This elaboration of the classical doctrine resonates with Marx's early emphasis on the domination of the producers by the products of their own labor and also has important ramifications

363

for the socialist agenda; it is not enough for the workers to own collectively the means of production, they must also control it, which implies not only a democratic state but also a democratic enterprise. The failure of that vision to survive the test of practical politics in the twentieth century, in both East and West, has motivated continuing efforts to rethink Marxist class theory. Nevertheless, the political systems of most of the industrial democracies are closely tied to class-specific constituencies, and Marx's seminal contribution remains the single most important intellectual influence on contemporary applications.

The neo-Marxist distinction between ownership and control owes extensively to a prominent non-Marxist, Ralf Dahrendorf, who argued that property is merely a special case of a more fundamental class relation based on authority. Dahrendorf's command class may be found not only in the process of production but in all 'imperatively coordinated associations,' including schools and churches. While this seems to imply an even broader and more radical agenda for the class struggle, Dahrendorf draws the opposite conclusion. The ubiquity of the command class means that opportunities exist for subordinates in one sphere of social life to serve as bosses in another. These cross-cutting cleavages suggest not class polarization but rather a pluralist model of highly stable industrial democracies.

The German sociologist Max Weber, whose stature in class theory rivals that of Marx, also challenged the assumption that class societies tend towards polarization and irreconcilable conflict. Weber countered that property relations need not correspond to other dimensions of social stratification, namely political power and social prestige; that is, the correspondence between class, status, and power is empirically and historically variable.

Marxists from the second half of the twentieth century generally agree, but insist that there are structural, economic limits on the political power of the working class, even where labor parties have enjoyed decades of uninterrupted political rule, as in social democratic Sweden. Efforts to redistribute profit and protect workers from the threat of the sack ultimately confront the inexorable logic of the competitive market, a conclusion that conservative economists readily affirm.

Weber also broadened the Marxist notion of property. Like Marx, Weber believed that '"Property" and "lack of property" are ... the basic categories of all class situations' (1978: 927). By this Weber means specifically a market situation, that is, a bargaining position in markets for labor, capital, or credit. Like Marx, Weber saw the propertyless as powerless in the bargaining encounter, but he differs in that his notion of property is more nuanced. For Weber, Marx's proletariat is not one but two classes,

those who possess a marketable skill and those with only their raw labor power to sell. The bargaining power of the unskilled laborer is vastly inferior to that of the expert machinist. Weber thus introduces the idea that knowledge, educational credentials, and skill can be marketable assets comparable to physical means of production and therefore relevant to the differentiation of classes. This has become one of the primary interests of contemporary class theorists, with important implications for the role of language, to be addressed momentarily.

As Weber seems to have recognized, his theory of market situation suggests gradational stratification rather than classification. The market capacities associated with the level of skill or the value of accumulated assets form a continuum with no intrinsically meaningful categories. In what sense then can Weberian classes be understood as qualitatively distinct? The solution proposed by Weber is the concept of *social* class based on the probability of movement from one position to another. Social classes can then be differentiated within a continuum of market capacities by mobility patterns: 'the totality of those class situations within which individual and generational mobility is easy and typical' (1978: 302). Social classes are thus characterized by common socioeconomic backgrounds as these open/restrict access to a given set of market positions. While inherited wealth may be the most obviously important, what has fascinated class theorists of the late 1980s and early 1990s is the inheritance and accumulation of cultural capital: educational credentials, knowledge and skill in the symbolic manipulation of language and figures, verbal style and proficiency, cultural taste, and knowledge of how to play the educational game.

3. Classes of Persons and Classes of Positions

Weber's distinction between economic classes defined by market situation and social classes bounded by mobility barriers introduces a dimension of class analysis that is largely missing from Marxist accounts: the social and cultural backgrounds of the incumbents of class positions. For Marxists, it is the inequality of positions within the social division of labor, and not the inequality of persons in access to those positions, that motors history. Hence 'individuals are dealt with only in so far as they are the personifications of economic categories, embodiments of particular class-relations and class-interests' (Marx 1978: 297).

This approach has informed numerous empirical studies that demonstrate pronounced differences in political and ideological alignment that reflect the interests inscribed in what structuralists call the empty places of the division of labor, empty in that it matters not who fills them. Simply put, the job makes the man, independently of the social and

cultural orientations that incumbents may bring with them to their positions. Put the children of workers in executive positions and they will think and act not like their parents but like their golf partners. Hence, social closure and class inheritance are not necessary to reproduce the class structure.

Writers working in the Weberian tradition, on the other hand, are more likely to think in terms of classes of persons defined by their access to valued resources, not classes of positions defined by locations in the social division of labor. Persons, as the units of class analysis, provide the nodal points at which the vocational dimensions of class intersect with inequalities outside the workplace, like differential access to marriage partners, private clubs, residential neighborhoods, and social networks. From Hollingshead's Elmtown to Warner and Lunt's Yankee City, these classic studies aggregate classes from the similarities of personal attributes affecting individual life-chances and social standing, in which family and education, as well as wealth and occupation, are what usually matter.

In broad strokes, this theoretical perspective places the social and cultural composition of classes at the center of class analysis and draws particular attention to problems of social mobility and status attainment. Incumbents do more than vivify their parts in a structural *deus ex machina*. Classes differ in their ideology, life-style, and voice because they systematically recruit incumbents with distinctive social and cultural backgrounds. Social closure is therefore essential to the reproduction of class. While acknowledging the Marxist canon that classes 'share a common function in the broad social division of labor,' the Ehrenreichs reject what they see as a 'vocational approach to class,' because it 'leaves out everything else which shapes a person's political consciousness and loyalties—their . . . social and cultural existence' (Ehrenreich and Ehrenreich 1979). Social closure based on exclusionary practices also entails intentional collective action, such that consciousness is a constitutive element of social class and not an epiphenomenon as assumed by structural Marxism, an approach that the eminent British sociologists Anthony Giddens and Frank Parkin claim vitiates class as a tool of empirical analysis. It is not incumbency of position in a formally defined structure but rather the organized effort to monopolize and usurp access that usually corresponds to political alignment and behavior.

Personal attributes that typify locations may also produce an association between persons and positions such that members acquire the class outlook of the positions typified by their background—the positions where they 'belong' as signified by their cultural marker. Members of an ethnic or other cultural collectivity historically associated with particular places in the division of labor may identify with the position signified not by where they are but by who they are, that is to say, not by their own class-structural location but by the location of those persons with whom they associate and typically interact. For example, one widely cited study suggests that middle-class blacks are more likely than whites in comparable class locations to identify with the working or lower class. Studies of overeducation have also found that college-educated respondents are more likely to identify as middle or upper class than others in similar blue-collar occupations, suggesting that membership in the middle class is based on the possession of credentials and not actual location in the social division of labor.

4. Knowledge Workers on the Road to Class Power

The rise of the new middle class is clearly one of the most important changes in the class structure of the advanced industrial societies, both East and West. The class is new in that its members derive their power, prestige, and overall life chances not from the sale of material commodities, as did the old petty bourgeoisie of family owned and operated businesses, but as salaried knowledge workers.

The term 'new class' was first proposed by Djilas in his pioneering work on the former state elites in Eastern Europe. The term was imported to the West by theorists of postindustrialism who broadened the concept to refer to structural changes in the social division of labor in both the public and private sectors: the separation of ownership and control, the growth of the public and nonprofit sectors, and the increasing centrality of highly specialized knowledge. The rapid ascension of these new administrative and professional positions has aroused the hopes and fears of left and right as they hazard the prospects of a robust and liberal counterweight to the political influence of business. Prominent neoconservatives like Peter Berger and Irving Kristol predict a political inversion in which these purveyors of symbolic knowledge supplant the proletariat as the major antagonists of capitalism. Others, including some neo-Marxists, claim only that large sections may be a potentially vital (if unstable) ally of the working class in countering the power of propertied interests (Wright 1979).

New-class opposition to corporate prerogatives, market logic, and entrepreneurial values has been attributed to the material interests of credentialed knowledge workers who find their road to power and privilege blocked by the propertied class, much as the bourgeoisie once confronted an older aristocracy. Those 'with an interest in having privilege based on educational credentials,' Berger hypothesizes, tend toward 'a general antagonism . . . against the capitalist market system that, in principle, is open to anyone regardless of education' (1986: 69–70). Moreover, 'like all rising classes, the knowledge class

rhetorically identifies its own class interests ... with the down–trodden (just as the early bourgeoisie did in its conflict with the *ancien régime*).' This opposition is reflected in and reinforced by what Alvin Gouldner (1979) has called a 'culture of critical discourse' that questions tradition, deference to authority, inherited privilege, and the voice of money rather than reason.

Neoconservative writers have also emphasized the role of the state as the Trojan horse of the intellectuals on the road to class power. As Berger argues, the growth of the state and nonprofit sectors provides the structural basis for the emergence of a counterelite that opposes propertied interests and supports state intervention on behalf of those perceived as victims of market inequity. Those whose work and advancement is not governed by the logic of commodity production may be less likely to accept the necessity or desirability of profit-centered activity and more disposed toward criticism of entrepreneurial values. However, critics such as Daniel Bell and C. Wright Mills have sharply questioned the independence of managers and highly paid professionals from the propertied interests that support them and with whom they socialize and marry.

These controversies have animated a plethora of empirical studies by leading researchers, including Samuel Stouffer and Seymour Martin Lipset. Evidence abounds of widespread support among college-graduate professionals for left-of-center positions on social issues: personal freedom, racial and cultural tolerance, rights of women and minorities, environmental and consumer protection, and antimilitarism. However, there is little evidence to suggest that either higher education or professional position promote antipathy toward business or free enterprise or support for greater economic equality.

Framed by Gouldner's theory of a culture of critical discourse, consistent cross-national evidence of the subjective salience of occupational self-direction suggests a plausible interpretation of new-class dissent on social issues. Melvin Kohn, who pioneered these studies, has accumulated, over three decades and in a variety of countries in the East and West, a vast archive of evidence pointing to the psychological impact of the experience of self-directed work (Kohn 1977). His extensive research reveals striking class differences in the exercise of critical discourse: tolerance, intellectual skepticism, moral flexibility, openness to social change, and a critical orientation towards tradition and authority. Classes differ ideologically not only because incumbents have different material interests, but also because they experience systematically different social relationships, from which they draw different generalizations about the world and their relationship to it, minimizing the dissonance between the values inscribed in their occupational roles and those in the world

outside. Hence those required to submit in the workplace are uncomfortable with self-directed inquiry, situationist ethics, and scientific uncertainty, while those in jobs that entail the exercise of discretionary responsibility find moral majorities equally bothersome.

Although Kohn and his associates do not test the implications of their model for class differences on social issues, other studies find strong support for the effects of occupational self-direction in promoting greater openness to social change. However, there is no evidence that this extends to an antibusiness animus. The weight of the evidence so far leans heavily to the conclusion that the rising middle class provides a powerful constituency for social reform but is unlikely to challenge the power and privilege of the propertied class.

Others have suggested reversing the causal order in Kohn's model. The personality traits associated with occupational self-direction may instead be acquired long before entering the workplace, through processes of socialization in the home and school. In their influential critique of the educational system, Bowles and Gintis contend that middle-class families tend to have children in student-centered, inquiry-oriented classrooms that model the employee-centered social relations of the office. In contrast, working-class children are more likely to find themselves in teacher-centered schools oriented toward discipline and compliance, corresponding to the more authoritarian social relations of the shop floor. As a result, despite class similarities in native intelligence, schools reinforce psychic and cultural differences that limit both the aspirations and opportunities of the less privileged. This view of the educational system, not as the great equalizer but as the axial mechanism for class inheritance, has provided the point of departure for important sociolinguistic studies of class attainment.

5. The Theory of Discursive Capital

The rise of a new middle class, endowed with cultural rather than material assets, has altered the process by which class inequalities are reproduced over time. Although cultural stocks like educational credentials, knowledge, and manners are highly marketable, they differ from material assets in that they cannot be readily probated. As a result, family socialization and education have attracted considerable scholarly attention as vehicles of class inheritance. It is in this context that theories of linguistic class differences assume special prominence. Basil Bernstein's work on the accumulation of what he calls 'discursive resources' represents one of the leading contributions, as well as one of the most controversial (see *Code, Sociolinguistic*; *Bernstein, Basil*).

Following Emile Durkheim, the influential French sociologist of the late nineteenth century, Bernstein argues that a more complex and fully differentiated division of labor entails changes in family interactions and corresponding linguistic codes. The simpler the social division of labor, Bernstein writes, the more restricted the coding orientation. The more complex the social division of labor, the more elaborated the coding orientation. These distinct semiotic grammars in turn facilitate or restrict access to locations in the division of labor, thereby reproducing and legitimating class inequalities across the generations (1981: 327–32).

The theory begins with a Weberian concept of a positively privileged class whose position is based on the possession of marketable knowledge, skills, and credentials, with access largely controlled by the educational system. Bernstein argues that the family relationships in this class differ fundamentally from the interpersonal relationships in working-class families. The latter are characterized by closed, position-oriented family relations in which interactions are determined by ascribed status as parent–child and male–female. The closed, position-oriented working-class relationships foster communalized roles outside the family that require consensus among the interactants, shared cultural history, similarity of experiences, and common assumptions that family members do not need or want to articulate, a pattern Durkheim called 'mechanical solidarity.'

According to Durkheim, mechanical solidarity derives from similarities in roles and functions, in which common experiences and shared identities bind members to the collectivity, as exemplified by tribal systems. This contrasts with what he called 'organic solidarity,' which derives from highly differentiated, interdependent roles, with bonds based on mutual need rather than identity of position. Mechanical solidarity is centered on the group, within which members are interchangeable parts. Organic solidarity is centered instead on the indispensability of specialized roles, leading to what Durkheim called the cult of the individual.

This cult of the individual, Bernstein argues, is more likely to typify middle-class families. They tend to exhibit open, person-oriented interactions, in which decisions are open to discussion and criticism, with less deference to the position of the speaker. Roles are more flexible and status within the family is negotiated rather than ascribed. Hence children can shape their role in the family so as to reflect their individual social and cognitive attributes and unique experiences. The open, person-oriented middle-class relationships carry over into what Bernstein characterizes as individualized roles outside the family that permit and encourage differences among interactants in backgrounds,

cultural assumptions, and points of view (see *Role Theory*).

Bernstein also follows Durkheim in the emphasis he places on the social structuring of meanings and on their diverse but related contextual linguistic realizations. Bernstein's approach is thus diametrically opposed to the Whorfian school which sees language as primary to the structuring of social relationships, determining the conceptualization and ordering of experience. Here it is the other way around. Distinctive patterns of interpersonal relationships provide different opportunities for the use of language. The interpersonal relationships in which working-class children communicate involve 'restricted codes' in which the speakers rely on shared understandings, with implicit meanings that speakers find difficult to articulate directly. 'The most general condition for the emergence of this code is a social relationship based upon a common, extensive set of closely shared identifications, and expectations self-consciously held by the members ... The meanings are likely to be concrete, descriptive, or narrative rather than analytical or abstract ... there will be a low level of vocabulary and syntactic selection; and *the unique meaning of the individual is likely to be verbally implicit*' (Bernstein 1966: 256–7).

Conversely, the individualized roles of the middle-class family, where the intent of the other person cannot be taken for granted, are conducive to *elaborated codes*, with a more complex grammatical sentence structure and more subordinate clauses, adverbs, and adjectives. Communication among highly differentiated roles requires speakers to be more explicit about meanings, with fewer assumptions about the common base of knowledge and experience on which speakers might rely.

These elaborated codes in turn reinforce a self-directed relationship with others. 'The user of an elaborated code comes to perceive language as a set of theoretical possibilities available for the transmission of unique experience,' Bernstein continues. 'The concept of self, unlike the self-concept of a speaker limited to a restricted code, will be verbally differentiated, so that it becomes, in itself, the object of specialized perceptual activity.'

The argument has striking implications for theories of the new middle class. Gouldner, for example, cites Bernstein's concept of elaborated codes as key to the critical discourse of the intellectuals. The model also addresses Kohn's research on occupational self-direction, suggesting that linguistic elaboration may account for the widely observed correspondence between self-directed work and ideational flexibility, openness to change, tolerance of diversity, and intellectual skepticism. What appear to be the psychological consequences of occupation may turn out to be latent cultural attributes, embedded in

367

speech patterns, that incumbents bring with them to the job.

However, the major application of the model has been as an explanation for class differences in educational success. Elaborated codes facilitate expression of complex and abstract ideas valued by the school, while the grammatical structure of the restricted code inhibits logical reasoning, promotes inconsistency, and limits interest in generalization, thereby precluding discursive inquiry and compromising the probability of academic achievement. 'If a child is to succeed as he progresses through school,' Bernstein concludes, 'it becomes critical for him to possess, or at least to be oriented towards, an elaborated code' (1966: 259).

Bernstein's novel and provocative explanation for the meritocratic reproduction of class inequality has motivated a new cottage industry of empirical studies. Bernstein's own investigations report that British upper-class children are significantly more likely to use elaborated codes, passive voice, and first-person pronouns, even when nonverbal IQ is controlled. Another five-year British study found that compared to working-class mothers, middle-class mothers favor abstract and implicit definitions over explicit and concrete definitions, and favor open-ended, heuristic answers to children's questions. An Australian study of 96 high-schoolers showed distinct social class differences in verbal linguistic coding.

Nevertheless, many others have found that Bernstein's model fits the data rather poorly and have had difficulty replicating his results, especially outside the UK. One study of the speech of 39 British 11-year-olds found no rigidity in the lower working-class children's speech, nor persistence of any restricted and elaborated codes. Similar findings have been reported from Australia. An American study of written language usage of 100 high school freshmen found no relationship between parental socioeconomic status and word usage or sentence structure. Several other US studies have also failed to show any direct relationship between social class and children's verbal communicative styles. Neither social control strategies nor school achievement scores were differently related to elaborated and restricted variants. An Israeli study of formal and informal speech situations for 72 male 12-year olds found no support for the claim that lower class children have less access to an elaborated code.

Thorlindsson's (1987) study of 338 Icelandic 15-year olds represents one of the most thorough and exhaustive attempts to fully test Bernstein's model. Thorlindsson found that linguistic elaboration does not play its predicted role, with no significant association with either social class, family interaction patterns, or scholastic achievement.

These inconsistent results may indicate substantial measurement error in key variables like linguistic elaboration and child-centered family interactions. Investigators disagree over the need to test spoken versus written language, the use of formal and informal contexts, and whether young children or parents should provide data on parental roles in the family. Thorlindsson also suspects that Bernstein's findings among British children reflect peculiarities of British upperclass values as these are reflected in the schools.

6. The Deficit Controversy

The empirical problems have been overshadowed by the other major criticism of Bernstein's work. His theory has invited interpretation and sharp controversy as a deficit theory of academic failure among working-class youth. Deficit theories, critics charge, blame the victims for conditions that are imposed on them and over which they exercise no real control. Class inequalities may then be rationalized as natural expressions of innate differences rather than outcomes of a competitive struggle.

Critics such as Gecas complain that restricted codes imply that the user could be expected to have lower cognitive abilities of abstract reasoning and analytic thinking. Bernstein is thus regarded as lending support to controversial theories of cultural inferiority such as those of Bereiter and Engelmann who hold that the dialect of blacks in the USA is not merely an underdeveloped version of standard English, but basically a nonlogical mode of expressive behavior.

Although Bernstein has been roundly criticized for advocating a deficit interpretation, it is clear even in his early writings that this is a serious distortion of his intent. Bernstein never contends that working-class children are cognitively deficient but only that they lack the opportunities for language use that middle-class children experience. To begin with, restricted codes are used at some time by all members of society, Bernstein emphasizes, including the middle class. 'Children socialized within middle class and associated strata can be expected to possess both an elaborated and a restricted code; while children socialized within some sections of the working class strata, particularly the lower working class, can be expected to be limited to a restricted code' (1966: 259).

This limitation is not a matter of ability. Working-class children are fully capable of using elaborated codes but lack opportunities to do so. Those thrust into highly differentiated roles have no choice but to respond to the needs for specialized communication inscribed therein. 'The orientation towards these codes, both elaborated and restricted, may be independent of the psychology of the child, independent of his native ability,' Bernstein continues, 'governed entirely by the form of

the social relation, or more generally by the quality of the social structure.' The problem is not innate ability but rather unequal access to different speech systems based on status position in a given social structure, such that children may adopt quite different social and intellectual procedures, despite a common potential. Thus Bernstein concludes that:

> The relative backwardness of lower working class and rural children may well be a form of culturally induced backwardness which is transmitted to the child through the linguistic process. The code the child brings to the school symbolizes his social identity. It relates him to his kin and to his local social relations. The code progressively orients the child towards a pattern of relationships which constitute for him his psychological reality, and this reality is reinforced every time he speaks.

In his later work, Bernstein underscores the point that the differences are based on power, not cognitive function. Using less neutral terminology, Bernstein argues that class relations 'generate, distribute, reproduce, and legitimate distinctive forms of communication, which transmit dominating and dominated codes...[that function as] culturally determined positioning devices' (Bernstein 1981: 327).

For example, Labov's (1972) study of language use among black gang members suggests that the experimental setting can generate the linguistic deficit that the investigator is seeking to measure. Labov found that when an inner-city black child is interviewed by an educated white person using elaborated codes, the child defends himself against what is perceived as an unsympathetic and probably hostile person by resorting to monosyllabic expression and minimal response. Labov then replaced the interviewer with an unthreatening black person who allows the child's best friend to come along and who sits on the floor with the children and shares a snack. The child then becomes verbally enterprising and shows no cognitive deficiency. Labov concludes that the social situation is the principal determinant of verbal behavior. Once this is taken into account, street dialect appears to be structurally equivalent to standard English, the speech patterns merely alternative expressions of the same latent linguistic construction (see *Ebonics and African American Vernacular English; Sociolinguistic Variation*).

Other studies also call into question the assumption that working-class children are victims of class-based socialization patterns. In his compelling ethnography of a white working-class gang in a British factory town, Willis (1977) shows how the gang members construct what he calls a counterschool culture in active defiance of dominant patterns that threaten their gendered self-esteem. The boys do not passively adopt coding orientations that handicap them in the schools; they not only know how to use elaborated codes, they delight in exaggerated mimicry of the ineffectual ambience projected by 'proper' expression. From this perspective, the concreteness of their discourse expresses their potency, while the official language of the school provides an endless source of ridicule that delights the boys and ritually affirms their masculine prowess. The paradox is that the boys are condemned to follow their parents into stultifying and low-paying jobs not because the school fails to appreciate their obvious ability and creativity, but because they reject the school as a scam designed for fools and a threat to their authenticity as concrete actors. To return to Marx, it would seem that the inversion of subject and predicate in the world of work leaves the boys with no choice but to speak in their own voice, a voice that mocks the ineffectual white-collar world and celebrates the robust efficacy of manual labor, echoing the sturdy proletarians depicted in the murals of socialist realism. But the celebration is cut short when the boys soon discover that life does not imitate art.

Social Networks

A. L. Milroy

Dialectological and historical linguistic research has consistently revealed the persistence, often over centuries, of low status and nonlegitimized dialects and languages in rural and urban communities, despite pressure from powerful standard languages like English and French. In contemporary western society where nonstandard dialects are publicly and generally stigmatized, such pressure is exerted in many ways—for example, through the educational system, through social and economic penalties springing from public use of nonstandard dialects, and through the language used and attitudes expressed in the broadcast and printed media. An individual's social network is quite simply the sum of relationships which he or she has contracted with others, and social network analysis examines the differing structure and properties of social networks. Such analysis has been applied in dialectology to explicate the day by day social mechanisms which allow speakers to maintain their nonstandard dialects, despite pressure from national standard languages. Conversely, change in the operation of these social mechanisms has been used to elucidate the phenomenon of linguistic change.

1. The Concept of Social Network

Social network analysis of the kind which is particularly relevant to dialectology originates in anthropological research, mainly during the 1960s and 1970s (see Li 1996). Scholars from many different disciplines employed the concept for a range of theoretical and practical reasons; Johnson's (1994) survey alludes to a wide range of approaches within anthropology, which hardly overlap with the largely quantitative modes of analysis described by Cochran et al. (1990). Procedures for analyzing the social networks of individuals were developed as a result of dissatisfaction with what some anthropologists saw as an overreliance on highly abstract social concepts (such as that of social class) in accounting for differences in everyday social behavior. Personal networks were generally seen as contextualized within this broader social framework, which constantly constrained behavior. However, it was 'bracketed off' to allow attention to be concentrated on developing less abstract modes of analysis which could account more immediately for the variable behavior of individuals. A fundamental postulate of network analysis is that individuals create personal communities which provide them with a meaningful framework for solving the problems of their day to day existence (Mitchell 1986: 74), and this kind of

focus makes it very suitable for studying small and relatively well-defined urban and rural communities.

A social network may be seen as a boundless web of ties which reaches out through a whole society, linking people to one another, however remotely. But for practical reasons social networks are generally 'anchored' to individuals, and interest focuses on relatively 'strong' first-order network ties—i.e., those persons with whom an individual directly interacts. Second-order ties are those to whom the link is indirect (see Fig. 1). This principle of 'anchorage' effectively limits the field of network studies, generally to something between 20 and 50 individuals. Thus, for example, if the objective was to look comparatively at the network structures of 40 speakers of a nonstandard urban dialect, one way to proceed would be to discover the 20 individuals whom each saw as his or her most significant daily contacts. Then the contrasts between these various 'networks' of 20 could be examined with respect to linguistically relevant characteristics such as whether they were dialect speakers or not, kin or not, had contacts with each other or not, and so on. In fact this is parallel to the procedure adopted by the social anthropologist Clyde Mitchell in a 1980s study of homeless women in Manchester, UK. His interest is in the effects of their personal network structures upon the length of time they are homeless. A different way of examining network structure is described in Sect. 2.

1.1 Multiplexity and Density as Properties of Networks

The two concepts of 'multiplexity' and 'density' are of critical importance in a comparative analysis of social networks. In a maximally dense and multiplex network, everyone would know everyone

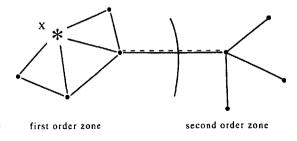
first order zone   second order zone


Figure 1. High-density personal network structure, showing first and second order zones. X is the focal point of the network.
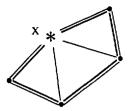

Figure 2.1 High-density, high-multiplexity personal network structure: X is the focal point of the network.
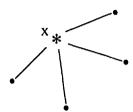

Figure 2.2 Low-density, uniplex personal network structure: X is the focal point of the network.

else (density), and the actors would know one another in a range of capacities (multiplexity). Social anthropologists now generally agree that a social network of a dense, multiplex type, which in effect constitutes a bounded group, has the capacity to impose general normative consensus upon its members. The idealized maximally dense and multiplex network is shown in Fig. 2.1 in contrast with a loose-knit, uniplex type of network (Fig. 2.2). Close-knit networks, which will of course vary in the extent to which they approximate to such a representation, have the capacity to maintain and even enforce local conventions and norms—of dress, religion, and general behavior, for example—and linguistic norms are no exception to this generalization. Close-knit networks are very common worldwide in low-status communities, both rural and urban, and they flourish in the absence of social and geographical mobility. It has been argued that close-knit networks with their characteristic reciprocity and solidarity ethic constitute a basic survival and support mechanism in poor communities in the absence of material resources. It will be shown in Sect. 2 how the characteristics of such networks are important in encouraging the long-term survival of socially disfavored dialects.

2. Social Networks and Language Variation

In this section some applications of the network concept in dialectology will be described, with particular reference to small-scale close-knit communities. Particular attention will be given to a study carried out in the mid-1970s of the urban dialect of Belfast, Northern Ireland (see Milroy and Milroy 1978, Milroy 1987). This research is in the quantita-

tive tradition developed by William Labov (see *Sociolinguistic Variation; Labov, William*). Using the concept of the sociolinguistic variable, the language patterns of 46 speakers from three inner-city communities were examined. Eight phonological variables (seven vowel variables and one consonant variable) were selected for analysis in relation to the network structure of individual speakers; all were quite characteristic of the dialect. Speakers varied, however, in the extent to which they used the vernacular realization of these variables; they were not isolated individuals, but had contracted long-standing social ties with each other within their neighborhoods. All three communities, Ballymacarrett, Clonard, and Hammer, were poor working-class communities where the informal social structure corresponded to the dense, multiplex, often kin-based patterns, described by many investigators as characteristic of long-established working-class communities (see, for example, Young and Wilmott 1962). The communicative pattern which recurs in these accounts is one of persons interacting mostly within a clearly-defined territory, tending to know each others' social contacts (i.e., having relatively dense social networks) and tending to be linked to each other by multiplex ties.

Although this dense, multiplex network structure was evident in all three communities (in very sharp contrast to middle-class neighborhoods) the extent to which individuals were linked to local networks varied considerably. Some people, for example, worked outside the area and had no local kin and no local ties of friendship, while others were linked to local networks in all these capacities. These differences in personal network structure, which appeared to spring from many complex social and psychological factors, were related to a number of other variables, such as the age and sex of the speaker and the type of locality. For example, young men seemed on the whole to contract denser and more multiplex network ties than young women, and urban redevelopment programs which relocated communities in outer urban areas seemed to have the effect of disrupting long-term network ties. Social network structure is also class-related in that middle-class networks are more frequently loose-knit. This point is returned to below.

2.1 Measuring Social Network Structure

Although when considered in terms of their social class they formed a very homogeneous group, the Belfast working-class speakers varied in their use of the linguistic variables, some sounding very much more vernacular than others. The device used to examine the relationship between this linguistic variation and variation in network structure was a six-point network strength scale which measured speakers' network characteristics on various

371

indicators of multiplexity and density. Two examples of these indicators are kin orientation and territorially based friendship ties (see Milroy 1987: 141 for full details). Since this network strength scale quantified the extent to which speakers interacted with others in the community and the strength of the ties contracted there, it could be interpreted as a measure of the pressure exerted by the close-knit network upon its members. A series of statistical tests revealed a strong correlation between personal network structure and patterns of language use, even allowing for the interaction of other social variables such as the age and the sex of the speaker; the strongest dialect speakers were those whose informal social ties were the strongest. Figure 3 illustrates their relationship in Ballymacarrett, in showing a tendency for speakers who are plotted high on the vertical axis also to be plotted towards the right of the graph. The linguistic behavior at issue is the presence versus absence of the consonant [ð] intervocalically in such words as *mother, brother*. Deletion scores for each speaker, whose age group and sex are also specified, are plotted as percentages against his or her network strength score. It is on the basis of such language/network relationships that the close-knit network may be viewed as an important social mechanism of dialect maintenance, encouraging the long-term survival of nonstandard and socially disfavored language varieties.

2.2 *Applications of the Network Concept in Small-scale Communities*

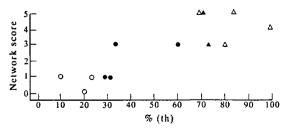
Apart from its potential for explaining why nonstandard dialects persist, a network approach has been found methodologically useful for investigations of subgroups in the population in situations where a social class model such as that provided by William Labov (1972) in his study of the urban dialect of New York City is less practical. This happens when the class distribution of the speakers to be studied is uneven, as is the case with most nonstandard dialect speakers. A network analysis has several rather obvious methodological advantages in such situations, which can be stated quite briefly. First, it provides a useful means of studying relatively


Figure 3. Ballymacarrett—individual scores on network strength scale.

small, self-contained groups in more detail than is possible within a large-scale survey framework such as Labov's. Second, it provides a means of approaching an analysis where the concept of social class is difficult to apply; this is a problem commonly encountered by researchers studying minority ethnic groups, migrants, rural populations, or populations in nonindustrialized societies (see, for example, Horvath 1985). Finally, network analysis offers a procedure for dealing with variation between speakers at the level of the individual rather than the group. These points are all relevant to the studies by Edwards (1986) of the language of British black adolescents and by Bortoni-Ricardo (1985) of changes in the language of rural migrants to a Brazilian city. A brief review of these studies follows.

One of the limitations on choice of method encountered by Edwards was that since there is no enumerated list of British black persons (even assuming that this is a well-defined category), a sample frame could not be constructed to allow speakers from the British black community to be systematically sampled from a range of social classes. Even if the use of social class as a speaker variable were feasible in this rather fundamental practical sense, it would in any case be unlikely to yield much insight into the interplay between social and linguistic differentiation. This is for the rather obvious reason that a social class index cannot distinguish in an illuminating way between members of a group who are mostly unemployed or concentrated in low-status occupations. But since it seems to be possible to analyze the black community as a whole as consisting of overlapping sets of relatively close-knit groups, the network variable is, as Edwards found, rather more helpful in describing the relationship between linguistic variability and the social characteristics of speakers.

The crucial variable from a dialectologist's point of view underlying any measure of personal network structure is degree of integration into a close-knit group. However, the same indicators (see the description in Sect. 2.1 of two of those used in Belfast) are not necessarily relevant to different groups. Even if attention is confined to the UK, membership of groups associated with religious institutions might well be irrelevant in a contemporary northern English coal-mining community, but highly relevant in a Midlands' black community such as the one Edwards studied. In fact the indicators used by Edwards were chosen for their capacity to distinguish between individuals who associated themselves to varying degrees with the norms and values of the black community; of particular importance is the distinction between black and nonblack ethnicity. For this reason, Edwards' indicators were designed to measure in various ways the extent to which speakers had contact with black

friends and neighbors and participated in black social activities. Whether or not the speakers were employed at all was also taken into account, since employment will almost always involve fairly extended interaction with nonblack individuals. In fact, the index of integration into the black community which was constructed using these indicators correlated well with the extent to which the individual speakers used the 'patois' characteristic of that community.

Bortoni-Ricardo's account of the sociolinguistic adjustment of rural migrants to Brazlandia, a satellite city of Brasilia, is a particularly interesting and innovative application of the network concept. A survey based on a social class analysis is not appropriate or feasible for a sociolinguistic study carried out in Brazil; the chief objections are that the notion of a continuum is neither congruent with the sharp distinction between rich and poor, nor does it adequately discriminate between the individuals studied, all of whom were relatively poor. Bortoni-Ricardo did not posit a linguistic movement by the migrants in the direction of an urban standardized norm (of Portuguese) of the kind familiar in studies using the social class variable; taking the group's own linguistic norms as a starting point, she examined the extent to which speakers had moved away from their stigmatized Caipira dialect.

Bortoni-Ricardo's main hypothesis about change in social structure associated with the change from rural to urban life is that it involves a move from an 'insulated' network consisting largely of kinsfolk and neighbors to an 'integrated' urban network where the links will be less multiplex and associated with a wider range of social contexts. The linguistic counterpart of this process is analyzed as one of dialect diffuseness—a movement away from the norms of the Caipira dialect. Two separate network indices are used to measure the changing patterns of the migrants' social relationships; the first is the integration index and the second the urbanization index. The integration index expresses numerically certain relevant characteristics of the three persons with whom each migrant most frequently interacts—for example, whether or not they are kinsfolk, or whether the ties have been contracted in the premigration period. The score assigned to each migrant is intended to characterize progress in the transition from an insulated to an integrated type of network, and as such is a tool capable of investigating loose-knit types of personal network structure (see further below). As Bortoni-Ricardo shows, integration scores correlate with a linguistic movement away from the norms of the Caipira dialect.

The urbanization index is designed to supplement this structural measure, representing the extent to which the members of each migrant's personal network are integrated into urban life. A number of indicators are used to compute this index, two of which are educational level and occupational mobility; the indicators are selected for their capacity to measure the extent to which the persons with whom a migrant customarily interacts is integrated into (i.e., participates in) urban life.

From both a methodological and a theoretical point of view, Bortoni-Ricardo's work is particularly interesting. In developing two types of index it extends the application of the network variable beyond an analysis of small, close-knit groups of the kind described so far to consider the extent to which individuals have detached themselves from such groups. The theoretical significance of this advance is explored below. Section 3 will concentrate on the theoretical implications of the link between a close-knit network structure and language maintenance and its obvious corollary; that a loosening of close-knit ties is likely to be associated with linguistic change.

3. Strong and Weak Network Ties: Theories of Language Maintenance and Language Change

A general methodological problem associated with the use of the network variable is that although it can be readily operationalized as described above to study speakers whose networks are of a relatively close-knit type, it cannot easily handle socially and geographically mobile speakers whose personal network ties are not predominantly dense or multiplex. However, such persons make up a substantial proportion of the population in a postindustrial society, particularly in cities. Loose-knit networks are hard to deal with chiefly because social network analysis involves comparing speakers who differ from each other in certain respects—for example, in respect of the multiplexity of the ties which they have contracted at the workplace—but are still similar enough in other related ways to make such a comparison meaningful. For example, it is evident that relative to someone who has changed employment and place of residence several times, the networks of the Belfast inner-city speakers described in Sect. 2.1 are all close-knit. While one might make this general point and follow through its implications in a comparison of, for example, these speakers with residents of lower middle-class areas of the city, it is much less easy to see how the relatively loose-knit network structures of individual lower middle-class speakers might meaningfully be compared with each other. This problem was encountered in an attempt to apply social network analysis in the prosperous Berlin suburb of Zehlendorf (Dittmar and Schlobinski 1988).

In Belfast, language variation in two lower middle-class areas, Braniel and Andersonstown, was analyzed to supplement the inner-city studies

described in Sect. 2.1. Many of the Braniel and Andersonstown speakers owned cars and telephones, which they used as a means of maintaining important personal ties over long distances, but the capacity of these 'distance' ties to influence their behavior (linguistic or otherwise) is not clear. Some speakers seemed to be relatively exposed to standardizing mainstream influences, in that they had contracted few personal ties which were likely to exert normative pressure on their behavior; but in any case the geographical spread of the ties contracted by most Braniel and Andersonstown speakers made them difficult to investigate. In general, however, these individuals seemed less likely than the inner-city speakers to be subject to the pressures of their personal networks and more likely to be subject to a less localized outside influence, which in turn exposes them to external pressure from a linguistic standard.

3.1 The Importance of Weak Ties in Elucidating Linguistic Change

Loose-knit networks are likely to play an important part in the construction of a theory of linguistic diffusion and change, at the level of theory, although they are difficult to analyze empirically (but see the discussion above of Bortoni-Ricardo's study of rural immigrants to a Brazilian city). Following Granovetter's work (1973) Milroy and Milroy (1985) have argued that 'weak' and apparently insignificant interpersonal ties (of 'acquaintance' as opposed to 'friend,' for example) are important channels through which innovation and influence flow from one close-knit group to another, linking such groups to the wider society. To support this argument, a detailed quantitative analysis of the history and present-day distribution of three Belfast phonological variables is presented. The spread of one of them apparently across sectarian lines of demarcation to penetrate the dialect of young speakers is difficult to explain except in such terms. The change involved is a realization of a limited set of lexical items such as *pull, put, foot* with an unrounded rather than a rounded vowel. This weak-tie model of change and diffusion is also applied to account for the tendency of some languages to be more resistant to change than others (Icelandic versus English, for example), the general argument being that a type of social organization which is based on overlapping close-knit networks will inhibit change, while one based on mobility (for whatever reason), with a concomitant weakening of network ties, will facilitate it. Weak intergroup ties are argued to be critical in transmitting innovations from one group to another, despite the rather general commonsense assumption in sociolinguistic and dialectological work that strong ties fulfill this role. For example, in suggesting that the network concept is important for a theory of linguistic diffusion, Downes (1998: 155) assumes that it is strong ties which will be relevant, and Labov (1980: 261) presents a model of diffusion and change where the innovator is seen as an individual with strong ties both inside and outside a local group.

Although the idea that innovations are transmitted through weak network links may at first sight seem counterintuitive, a little thought suggests that it is plausible. First of all, it is likely (in the networks of mobile individuals at least) that weak ties are more numerous than strong ties. Second, many more individuals can be reached through weak ties than through strong ties; consider, for example, the links set up by participants at academic or business conferences, which link cohesive groups associated with each institution and through which new ideas and information pass. Conversely, information relayed through strong ties tends not to be innovatory, since those linked by strong ties tend to share contacts (that is to belong to overlapping networks). Thus, mobile individuals who have contracted many weak ties, but as a consequence of their mobility occupy a position marginal to any given cohesive group, are in a favourable position to diffuse innovation. Interestingly, this conclusion is in line with the traditional assumption of historians of language that the emergent, mobile merchant class were largely responsible for the appearance of Northern (and other) dialectal innovations in Early Modern (Standard) English (see, for example, Baugh and Cable 1978: 194).

The norm-enforcing capacities of groups built up mainly of strong ties partly explains why innovators are likely to be persons weakly linked to the group; indeed, using a measure of network strength, the Belfast community studies described in Sect. 2.1 showed that susceptibility to outside influence increased in inverse proportion to strength of tie with the group. Where groups are loose-knit—that is linked internally mainly by weak ties—they are therefore likely to be generally more susceptible to innovation. This conclusion is consistent with Labov's principle that innovating groups are located centrally in the social hierarchy, in his terms upper-working or lower-middle class (Labov 1980: 254). For it is likely that in British (and probably also North American) society close-knit networks are located primarily at the highest and lowest strata, with a majority of socially and geographically mobile speakers falling between these two points.

3.2 An Apparent Problem: The Weak Tie Model of Diffusion and Change

One apparent difficulty with a theory which argues that innovators are only marginally linked to the

group is in explaining how they can successfully diffuse innovations to more central members; two related points are relevant here. First, since resistance to innovation is likely to be strong in a norm-conforming group, a large number of persons will have to be exposed to it and adopt it in the early stages for it to spread successfully. Now in a mobile postindustrial society, weak ties are likely to be very much more numerous than strong ties. Thus, an innovation like the Cockney merger between /v/:/ð/ and /f/:/θ/ reported in Norwich teenage speech (Trudgill 1986: 54ff.) which appears to 'jump' over a considerable distance is likely to be transmitted through a great many weak links between Londoners and Norwich speakers. Trudgill's suggestion of tourists and football supporters as individuals who might contract such links and transmit the change is quite consistent with the model outlined in this section. Second, persons central to a close-knit, norm-enforcing group are likely to find innovation a risky business; but adopting an innovation which is already widespread on the fringes of the group is very much less risky. Thus, instead of asking how central members of a group are induced to accept an innovation from marginal members, this can be viewed as a prudent strategy on their part. For it is likely that a necessary (but not sufficient) condition for the ultimate adoption of a candidate innovation is that it is positively evaluated, either overtly or covertly. Thus, Norwich speakers, whether they are central or marginal to their local groups, in some sense view vernacular London speech as desirable—more desirable than the speech of other cities. Central members of a group diminish the risk of potentially deviant activity by adopting an innovation from persons who are already linked to the group, rather than by direct importation.

This weak tie model of linguistic change remains to be developed further. However, it seems to be capable of illuminating some puzzling patterns of variation and change which are difficult to explain in terms of the usual unqualified assumption that linguistic change is encouraged by frequency of contact and relatively open channels of communication, and discouraged by boundaries of one sort or another, or weakness in lines of communication.

4. Social Network, Social Class, and the 'Quantitative Paradigm'

An extension of network analysis which focuses on the properties of weak ties provides a crucial link with the variable of social class, which is used extensively in social dialectology to account for variation in urban dialects. Social anthropologists have linked the variables of class and network by arguing that class differences in small communities

begin to emerge over time as the proportion of multiplex relationships declines. Such observations suggest a route for constructing a two-level sociolinguistic theory, linking small-scale structures such as networks in which individuals are embedded and act purposively in their daily lives with larger scale social structures (classes) which determine relationships of power at the institutional level. Such a dual level of analysis is needed in order to understand the frequently reported tendency of speakers of urban vernaculars to downgrade their dialects (describing them as 'sloppy,' 'vulgar,' and the like) while nevertheless continuing to speak them in the face of intense standardizing pressure. Recall that while strong ties give rise to a local cohesion of the kind described in inner-city Belfast, they lead paradoxically to overall fragmentation. It is this potential for explaining both patterns—local stability and cohesion versus overall fragmentation and conflict—which allows network analysis to be related to macrolevel social structure.

Some comments made about network models assume that they cannot easily be linked with class-based analyses of language variation because they are concerned only with strong ties in close-knit communities. Network is frequently seen as a microsociological concept, while class is macro-sociological. While this is a reasonable point if network analysis is applied only to close-knit communities, an analysis of loose ties provides a link between the two levels. Furthermore, an initial concentration on network, which emphasizes the extent of local fragmentation in socially stratified societies, suggests that a social class model based on conflict is more appropriate for urban dialectological work than one based on consensus. A number of researchers have been critical of the currently widely accepted consensus model which underlies the work of Labov.

It was pointed out in Sect. 3 that an analysis which makes use of the weak-tie concept agrees with a Labovian class-based analysis in locating linguistic innovators centrally in the class structure. For in British and North American society at least close-knit networks are located primarily in the highest (most powerful) and lowest (least powerful) classes; with regard to the former, consider Mills' (1956) description of the USA power elite. The majority of socially and geographically mobile speakers falls between these two points. Thus, if a network analysis is extended to include an examination of loose-knit network types, which are susceptible to outside (frequently standardizing) influences, it is plain that network-based and class-based analyses are not contradictory as is sometimes suggested; rather they complement each other. This suggests the possibility of an integrated analysis of

375

the relationship between language variation and social structure, combining the variables of social class and social network. Such an analysis would present particular social groups as both internally structured and connected to each other with varying proportions of strong and weak ties.

4.1 Class-related Types of Social Network

The characteristic network structure of distinguishable social groups is certainly related to social class (see *Social Class*) variation (and indeed to other intersecting social variables such as gender and ethnicity) and is likely to have a powerful effect on the kind of dialect spoken both by individuals and by the group as a whole. For example, ethnic subgroups in the UK such as the black speakers studied by Edwards have a predominantly strong-tie internal structure, but seem to be linked with relatively few weak ties to white working-class groups. These white groups in turn might have a similar internal network structure but have more weak-tie links with other white working-class groups. Vertical links to middle-class groups are likely to be fewer (this seemed to be the case in Belfast) and moreover to be frequently institutional in content (to such persons as doctors, lawyers, teachers, welfare personnel, and the like). Middle-class groups for their part—professional, neighborhood, and friendship groups—are characterized by a higher proportion of weak ties internally than working-class groups; hence the problems of studying them systematically in network terms in Zehlendorf, Berlin, and in outer-city Belfast.

However, the controversial concept of social class is interpreted and however close-knit networks are investigated and described, Granovetter's concept of the weak tie can be used to link close-knit community level groupings to more abstract institutional structures. A network perspective on social dialects attributes the behavior of speakers to the constraining effects of the network, or the diminution of those effects which enables standardizing linguistic influences to permeate communities. This avoids a direct appeal to the notion of prestige as defined by the perceived attributes of speakers who are seen to *belong* to different status groups. Social class is viewed as a structural concept rather than a set of labels which might be attached to particular individuals. Thus, local and individual social and linguistic behavior is not seen as directly related to class but as mediated through smaller scale network structures.

Network analysis has recently been used by historical linguists to examine the social trajectories of earlier changes (Tieken-Boon van Ostade et al. 2000), and has been employed for a range of analytic purposes in many different kinds of contemporary monolingual and bilingual communities (see Milroy 2001 for a recent review).

Sociolinguistic Variation
R. Mesthrie

Sociolinguistic Variation

This article surveys the approach to linguistic variation taken by William Labov and the school of sociolinguistics that has stemmed from his influence. The work of this school is known by several other names, which give some indications of its main preoccupations: the quantitative paradigm, sociolinguistics proper, variationist studies and urban dialectology.

1. The Goals of Sociolinguistics

Prior to Labov's work in the early 1960s, dialectology had scored its main successes in studies of regional differentiation. Researchers had certainly been aware of linguistic distinctions of a social nature within a region, but had not developed systematic ways of describing them. Earlier explanations of nonregional variation fell into one of two categories: dialect mixture and free variation. 'Dialect mixture' implies the coexistence in one locality of two or more dialects, which enables a speaker to draw on one dialect at one time, and on the other dialect(s) on other occasions. 'Free variation' refers to the random use of alternate forms within a particular dialect (e.g., two pronunciations of *often* [with or without the /t/ sounded]). Both views relegate variation to an extralinguistic domain, and mistakenly identify structuredness with homogeneity. Labov argued, instead, that language involved structured heterogeneity. While he was not the first to point to the interplay between social and linguistic determinants of certain linguistic alternations (e.g., Fischer had discussed the social implications of the use of *-in* versus *-ing* in a New England setting in 1958), Labov was the initiator of an elaborate body of work which broke new ground in understanding language in its social context, accounting for linguistic change, and broadening the goals of linguistic theory. An important motivation in his early work was to understand one of the unsolved problems of historical linguistics—how sound changes like [p] > [f] are effected. He also wondered how, if a language has to be structured in order to function efficiently, people continue to talk while the language changes. The problem was shown to be less intractable once one invoked the idea of systematic variation among different groups of speakers within a speech community (see *Sociolinguistics and Language Change*). Labov's study of English on Martha's Vineyard provided strong evidence for the claim that native-like command of a language includes the control of heterogeneous structures.

2. An Early Study—Martha's Vineyard

The island of Martha's Vineyard off the New England coast was the setting of Labov's study (1963) of the significance of social patterns in understanding language variation and change. The island is inhabited by a small number of indigenous Indians, larger numbers of descendants of old families of English stock, and people of Portuguese descent. Furthermore, it is overwhelmed by tourist summer residents from the mainland. Among a range of phonetic characteristics of English on the island, Labov chose to study variations in the diphthongs /ay/ and /aw/, as in *white* and *out* respectively. Instead of the neighboring New England [aɪ] and [aʊ], these frequently have centralized elements ([ɐɪ] and [ɐʊ], or even [əɪ] and [əʊ]) on Martha's Vineyard. The variables (ay) and (aw) fulfill three criteria that make them focal elements in the study of language in its social setting: (a) they are frequent enough in ordinary conversation to appear unsolicited in brief interviews; (b) they are structurally linked to other elements in the linguistic system—that is, to the system of diphthongs in the dialect; (c) they exhibit a complex and subtle pattern of stratification by social groupings.

Labov undertook 69 interviews with native Vineyarders. These are relatively formal—involving a lexical questionnaire, a reading passage, and questions exploring the social orientation of the respondent, especially designed to elicit the (ay) and (aw) variables. Observations of casual speech in public settings served only as a supplementary check on the tape-recorded speech. The interviews thus did not involve the techniques that were to become synonymous with the Labovian paradigm.

There did not appear to be much style shifting in the interviews, perhaps because of the methodology (although Labov suggests that these were essentially single-style speakers). Variation was apparent along a number of dimensions including ethnicity, occupation, and geographical location. There was also a linguistic dimension to the variation in that centralization was favored in certain environments. If voiceless alveolar and labial elements (/t/, /s/, /p/, /f/) followed, centralization was most favored; if liquids or nasals (/l/, /r/, /n/, /m/) followed, centralization was least favored.

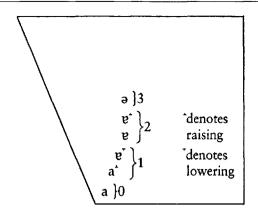
This article will concentrate on the most salient factor that shows covariation with centralization: age. In his analysis, Labov used a scoring system of 0 for [a], 1 for [a⊥] and [ɐ⊤], 2 for [ɐ] and [ɐ⊥], and 3 for [ə] (see Fig. 1). Averaging the values of all the tokens per age group, and expressing them as a


Figure 1. Variants of the first element /a/ in the diphthong in WHITE, RIGHT, KIND in Martha's Vineyard, and values assigned to them.

Table 1. Centralization index for Martha's Vineyard.

Age	(ay)	(aw)
75–	25	22
61–75	35	37
46–60	62	44
31–45	81	88
14–30	37	46

percentage of the total occurrence of each variable per age group yields the centralization index given in Table 1. Scores may thus range from 0 to 300: the higher the score, the greater the use of island variants rather than the general New England [a].

Table 1 shows an increase in island variants with a decrease in age, with the exception of the youngest group. A comparison with earlier records of the *Linguistic Atlas of New England* (LANE) undertaken by Kurath et al. in 1941, reveals that this is not a self-repeating age-graded pattern (as the use of slang might be, for example). The rest of this section will concentrate on the simpler case of the (ay) variable. The centralized form of /ay/ was once the more usual, going back to seventeenth-century England, and still recorded in moderate numbers in New England and Martha's Vineyard in the LANE records. Comparing LANE records with those of late twentieth-century Martha's Vineyard, it is evident that there had been an intervening drop in centralization. That is, Martha's Vineyard was once in line with the rest of New England in showing a decline in centralization; but the trend has been reversed, with younger people accentuating a pronunciation that was becoming less common in the speech of their elders. In answering the question of why younger people of Martha's

Vineyard seemed to be turning their backs on the history of English phonology, Labov appealed to social relationships between the inhabitants of the island (poor by American standards) and the rich summer residents. A high degree of centralization of (ay) and (aw) is closely linked with strong resistance to the incursions of the summer people, which have to be tolerated for economic reasons. It is especially since around World War II that the social and economic pressures have brought on this resistance among younger groups. Using a pronunciation like [rɐɪt] 'right' or [hɐʊs] 'house' is a subconscious affirmation of belonging to the island and being one of its rightful owners.

Although the oldest groups show reduced levels of centralization, the one resistant group was a group of fishermen from a part of the island called Chilmark. Labov argues that the ways of these Chilmark fishermen—independent and stubborn defenders of the old way of living—served as a reference point for those of the younger generation throughout the island who might be seeking an identity opposed to that of the tourists. Finally, in answering the question of why the 14- to 30-year-old group does not exhibit the revived island-centralization pattern, considerations regarding attitude and identity are again crucial. According to Labov's argument, these speakers do not feel the full stress experienced by the 30+ age groups, who have grown up in a declining economy, and who have made a more or less deliberate choice to remain on the island, or, having sought work in the mainland, have elected to return to Martha's Vineyard. The youngest group, which included many high-school pupils, either harbored hopes of going to the mainland or had not yet made their choice. This indecision is unconsciously reflected in their indices for the two sociolinguistic variables.

The Martha's Vineyard study shows that the Chomskyan characterization of linguistic competence with reference to an idealized speaker-hearer in a homogeneous setting is far too narrow. The rules of a language (and perhaps language in general) cannot be fully accounted for without examining their patterning over social space. Native-like command of heterogeneous structures is not necessarily a matter of multidialectism or 'performance,' but part of a unified linguistic competence. In the case of a language used in a complex society, it may well be that it is the absence of structured heterogeneity which would count as dysfunctional. In addition to expanding the goals of a Chomsky-dominated linguistics, Labov argued against the introspective methods of the generative school, where a researcher often used his or her idiolect as the only source of data. He stressed, instead, the importance of studying the vernacular speech of individuals in its community setting.

By 'vernacular' is meant the style of speech that one uses in the least self-conscious mode in informal settings, as when laughing and chatting with friends. It is the basic style of speech learnt in pre-adolescent years, which may be modified later on by other styles encountered at school and at work. Labov believed that the vernacular provided the most systematic data for linguistic analysis. This does not mean that it is devoid of variation: it may involve 'inherent variation'—that is, alternate forms belonging to the same system acquired simultaneously, or nearly so, at an early age. The rules governing variation in the vernacular appear to be more regular than those operating in formal, superposed styles acquired in postadolescence. Each speaker has a vernacular style in at least one language; this may be the prestige dialect (as in the case of standard English) or, more usually, a nonstandard variety.

Labov developed an empirical approach to the study of the vernacular that involved careful sampling of populations to ensure representativeness, fieldwork methods designed to elicit a range of styles from the least to the most formal, and analytic techniques based on the concept of the linguistic variable. The linguistic variable is an item which has identifiable variants: for example, one may consider the participial ending *-ing* to be a linguistic variable—written within rounded brackets as (*-ing*)—which has the variants [-ing] and [-in] in many dialects. Whereas the alternation between variants may sometimes depend purely on a linguistic context, the ones of greatest interest to sociolinguists are those which show social conditioning as well.

The Martha's Vineyard study was a clear and relatively simple illustration of the interplay between linguistic and social factors. In subsequent studies, Labov worked on more complex situations—large urban centers, and large populations with several ethnic groups, multiple-style speakers, and with rapid change and upward mobility.

3. Postvocalic (r) in New York City

This is Labov's most influential study, showing essentially that if any two subgroups of New York City speakers are ranked in a scale of social stratification, they will be ranked in the same order by their differential use of certain linguistic variables, most notably in their use of (r) after vowels in words such as *park* in casual speech styles. However, the influence of the study goes beyond mere correlation of variables—it contributed decisively to the development of a sociolinguistic methodology, fieldwork techniques, and the study of language change in progress.
